The scientific program was replaced by an entertainment in keeping with the occasion. This consisted of a travelogue, "Australia and Its Wild Nor-West" illustrated with motion

pictures, by M P Greenwood Adams of Australia.

The speaker told much of interest about that large but sparsely settled country and showed many pictures of the principal cities and of the wild north-west. Pictures of Melbourne revealed a large city of many beautiful buildings and parks. The motion pictures of Melbourne Handicap, the great horse race of the year, showed a crowd of 130,000 people attending the event. In contrast to the modern cities of Sydney and Melbourne were the pictures of the outlying parts of the island. Particular interest was given to the pearl industry which centered around the town of Broome with its 4,000 population. The pictures revealed divers at work gathering shell oysters and showed how they were opened and inspected for pearls which are in reality a product of the disease of the oyster. The shells of these oysters supply about three-quarters of the world's mother of pearl.

The pictures of the aborigines of the island were particularly interesting indicating as they did their habits and activities. Mr Adams' presentation was thoroughly appreciated by the 103 members and guests who were in attendance.

# THE DAILY PRESS

## KEEPING UP WITH THE TIMES

The medical profession is not the only one in which constant study is necessary in order to keep abreast of the discovery of new facts and new methods of their application. The *New York Herald Tribune* of June 2, commenting on the address of Dr G E Shambough before the American Medical Association, calls attention editorially to the intensive training which occupies all the time of the medical students, and contrasts that training with the lack of time and opportunity which confronts the young physician when he enters practice. The inevitable conclusion is that physicians cannot practice medicine and keep up-to-date in a knowledge of new developments. But the Editor says

"The same wail has been heard from other professions. All branches of learning have acquired these last few years enormous velocities. Engineers and artists, lawyers and business men, all lament that the progress of knowledge since the ending of their college days leaves them hopeless stragglers from the procession. There is no convenient and satisfactory way to keep up with the world, no translations. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$7.00

**THE DISEASES OF INFANTS AND CHILDREN** By J P Crozer Griffith, M.D., and A Graeme Mitchell, M.D. 2nd Edition, reset. Two octavo volumes totaling 1715 pages, with 461 illustrations, including 20 plates. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$20.00 net

**THE HARVEY LECTURES** Delivered Under the Auspices of The Harvey Society of New York. Series XXI, 1925-26. By Dr F R Nager, and others. Octavo of 229 pages. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$4.00

**A PRACTICAL TREATISE ON DISEASES OF THE SKIN** For the Use of Students and Practitioners. By Oliver S Ormsby, M.D. 3rd Edition thoroughly revised. Octavo of 1262 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$11.00

**DISEASES OF THE DIGESTIVE ORGANS** With Special Reference to their Diagnosis and Treatment. By Charles D Aaron, Sc.D., M.D. 4th Edition thoroughly revised. Octavo of 927 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$11.00

**A MANUAL OF GYNECOLOGY** By John Osborn Polak, M.Sc., M.D. 3rd Edition, thoroughly revised. Octavo of 402 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$5.00

**BACTERIOLOGICAL ATLAS** A Series of Colored Plates Illustrating the Morphological Characters of Pathogenic Micro-Organisms. By Richard Muir. 12mo of 14 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$4.50

"We wonder whether the solution, so far as science is concerned, does not lie in the amateur scientific society. A few days ago Dr G Clyde Fisher, of the American Museum of Natural History, issued a call for persons interested in an amateur astronomical society. Over five hundred responded, indicating an interest by no means small. Another New York organization, the New York Electrical Society, has made a distinguished record for the last three years in supplying this same need for continuing the education of college graduates, or of those by whom a college education was unobtainable."

The leaders of the Medical Society of the State of New York have a keen appreciation of the need of continual study by physicians, and they agree with the Editor that the instruction can best be accomplished through societies,—county societies—for physicians. The Committee on State Society Medical Education is doing a unique piece of work in bringing opportunities for medical study to the physicians in their own towns, instead of compelling them to leave their patients for days. Illustrated. Paris, Gaston Doin & Co., 1927. 30 Francs (Les Consultations Journalières)

**LES STUPÉFIANTS** Par le Docteur R. Porak. 12mo of 348 pages, illustrated. Paris, Gaston Doin & Co., 1927. Paper, 18 Francs

**OBSTETRICS FOR NURSES** By Joseph B De Lee, A.M., M.D. 8th Edition, revised. 12mo of 635 pages, with 266 illustrations. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$3.00

**HISTORY OF CARDIOLOGY** By Louis Faugeres Bishop, M.A., M.D. and John Neilson, Jr., B.S., M.D. With an introduction by Victor Robinson, Ph.C., M.D. Octavo of 71 pages, illustrated with portraits. New York, Medical Life Press, 1927. Cloth, \$5.00

**PROCEEDINGS OF THE NINETEENTH AND TWENTIETH CONFERENCES OF THE AMERICAN ASSOCIATION OF MEDICAL MILK COMMISSIONS** In Conjunction with the Certified Milk Producers' Association of America. Nineteenth Annual Conference held at Atlantic City, N J, May 25 and 26, 1925. Twentieth Annual Conference held at Dallas, Texas, April 19 and 20, 1926. Octavo of 340 pages. Brooklyn, N Y, 1926

**THE FIFTH AVENUE HOSPITAL CLINICS** First Series. Based on the Material from the Semi-Monthly Staff Meetings, 1925. By the Editorial Board. Octavo of 336 pages, illustrated. New York, Paul B Hoeber, Inc., 1927. Cloth, \$5.00

**THE MEDICAL CLINICS OF NORTH AMERICA** Vol 10, No 5 March 1927 (Boston Number). Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

# BOOK REVIEWS

**THE ESCAPE FROM THE PRIMITIVE** By HORACE CARN-CROSS, M.D. Octavo of 348 pages. New York and London, Charles Scribner's Sons, 1926. Cloth, \$2.50

In this book the author describes the evolution of the mind of modern man through the various stages of its development. He begins with a discussion of the family, treating it under the heading of *The Great Complex*. He then pursues a direct course, discussing such subjects as Mother Nature, Chance or Purpose, Instinct and Intelligence, Free Will and Fate, and finally Responsibility. In the second part, he treats of the mentality of the primitive man, and elaborates upon Magic, Father God, Primal Trends, and finally the New Dispensation, in which he discusses the genesis of modern theology. In the last part of the book, he traces the mental development of modern man, and analyzes the components of reality, love, ego, etc. The subject is dealt with in a comprehensive, philosophical manner, and is a real contribution to genetic psychology.

IRVING J. SANDS

**AN INTRODUCTION TO THE PRACTICE OF PREVENTIVE MEDICINE.** By J. G. FITZGERALD, M.D. Assisted by PETER GILLESPIE, M.Sc., C.E., and H. M. LANCASTER, B.A.Sc. 2nd Edition. Octavo of 792 pages, illustrated. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$7.50

This is the second edition of Dr. Fitzgerald's work follows closely the material in the first edition. However, it has been brought up to date by covering recent advances in preventive medicine.

The book is an admirable text for undergraduate medical students, if the contents is supplemented by lectures, demonstrations and laboratory work, otherwise many subjects are covered too briefly. Dr. Fitzgerald reflects the Canadian viewpoint regarding active immunization to diphtheria in that he almost ignores the use of toxin-antitoxin for this purpose and lays all the stress on toxoid. He at least leaves the inference that toxin-antitoxin contains elements of danger, this is not borne out by the work of Park who has had the largest experience with toxin-antitoxin. Furthermore, it seems to us that instead of giving the most important place in diphtheria prevention to active immunization the author almost makes it secondary to other means. Undoubtedly this was unintentional and we hope that in subsequent editions this will be corrected which is possible by a slight rearrangement of the text.

In dealing with rabies no mention is made of canine vaccination as a means of control nor is the Semple method of Pasteur treatment described. This method using as it does a killed virus has less danger than the original Pasteur treatment, but of most importance is the fact that the Semple vaccine is stable while the attenuated virus is perishable.

The chapters on water, community sanitation, maternal and infant mortality are especially to be commended.

E. H. M.

**DE LAMAR LECTURES 1925-1926** (Johns Hopkins University—School of Hygiene and Public Health) By DAVID MARINE, and others. Octavo of 220 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927. Cloth \$5.00

This is a collection of thirteen popular lectures on various subjects especially of interest to sanitarians and public health officers. The prominence of the lecturers, the subjects treated, and the place where the lectures were delivered, insures the reader of this volume much instruction as well as interest.

Dr. David Marine of the Montefiore Hospital treats

on "The Prevention of Simple Goiter", Professor Abner Hamilton gives the latest data on Industrial Toxicology in the United States, Dr. F. C. Wood lectures on "The Necessity of Education in Control of Cancer", Dr. Fredrick W. Sears on Rural Hygiene, Thomas Adams on Industrial Housing, Dr. W. G. Smilie on Hookworm Infestation, Dr. Edward R. Baldwin on Diagnosis of Tuberculosis, Dublin on Body Build and Longevity, Dr. Goldberger on Pellagra, Dr. Stockard on Constitutional Types in Relation to Disease, Dr. LoGrasso on Heliotherapy in Treatment of Tuberculosis, R. B. Stoeckel on Motor Vehicle Accident Prevention, and Newsholme on William Farr.

It is to be regretted that it is impossible in a brief space to give even a resume of the wealth of material and new thoughts with which the volume abounds. Dr. Hamilton's recent advances in industrial toxicology are especially of interest in view of the fact that the study of this subject is still in its infancy in this country. Dr. Hamilton briefly dwells on the toxicology of tetraethyl lead and states that "the danger involved in the production of this product and the process of mixing it with gasoline is abundantly proved" and hopes later that proper safeguards will be taken to prevent intoxication by it. Dr. Hamilton also mentions the latest researches which seem to show that the action of silica particles in the lungs is not of a physical mechanical character, but rather of a chemical and therefore toxic character, and perhaps we should include silica dangers under the industrial poisons.

Professor Stockard's lecture on "Constitutional Types in Relation to Disease" is very illuminating and stresses the idea of the need of knowledge by the physician of the constitution of the patient in his efforts to control and alleviate disease.

G. M. P.

**MODERN MEDICINE. Its Theory and Practice in Original Contributions by American and Foreign Authors.** Edited by SIR WILLIAM OSLER, Bart., M.D. Third Edition, thoroughly revised. Re-edited by THOMAS McCRAE, M.D. Assisted by ELMER H. FUNK, M.D. Volume 4. Diseases of the Respiratory System—Diseases of the Circulatory System. Octavo of 1011 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$9.00

Volume IV of this edition of *Modern Medicine* is devoted to a consideration of diseases of the respiratory system (except pneumonia and tuberculosis) and diseases of the circulatory system. A proper balance is struck, although the allotment of 200 pages for Maude Abbott's chapter on congenital cardiac disease seems excessive, as only 625 pages are available for the second part of the volume.

There is much material of value presented by the distinguished contributors. The press work is splendid and errors conspicuous by their infrequency. Rackemann is manifestly wrong in stating on page 96 that Bethlehem, Bretton Woods and Dixville Notch are at an elevation of 4,000-5,000 feet. The elevation is certainly not greater than 1,400-1,500 feet. He also fails to mention the Chinese drug Ephedrin in the treatment of bronchial asthma.

The average excellence of the chapters is very satisfying. F. T. Lord is outspoken in saying that primary dry pleurisy as well as serofibrinous effusion should be regarded as tuberculous in the vast majority of cases, and quotes his experience in treating pleurisy with effusion when the fluid was turbid and containing an excess of polymorphonuclear cells of 27 cases, 15 were cured by thoracentesis alone. His description of the Koranyi-Grocco paravertebral triangle of dullness is good.

Landis' discussion of the antagonism of the diaphragm and the intercostal muscles clearly states present day opinion (page 335)

The introductory chapter to the Section on Circulatory Diseases is by Hoover who pleads for us to use our fingers more lest we become "witless servants of our instruments" He urges direct percussion with the tip of the extended finger in outlining the heart His presentation of the estimation of the heart's volume, hepatic displacement, air hunger and slumber apnea is very thorough.

McPhedran (page 370) emphasizes that if pericardial effusion is slow in formation, it is rarely embarrassing to the heart even if very large.

Lewis' rules for the administration of quinine in fibrillation (page 419) are very valuable and constitute the best guide to its use that the reviewer has yet seen He proposes every safeguard, but even then warns against the possibility of embolism Hemoptysis, venous engorgement and much enlargement of the heart are to be considered as definite contraindications to its use.

If the other volumes of this edition are the equal of this one, Modern Medicine has maintained its high ranking

FRANK BETHEL CROSS

**THE ENLARGED PROSTATE.** By KENNETH M WALKER, F.R.C.S Octavo of 193 pages, illustrated. London and New York, Oxford University Press [1926] Cloth, \$4.00 (Oxford Medical Publications)

This is one of the best *little* books we have ever read The arrangement is excellent, the illustrations are good and, in the brief space of less than two hundred pages the writer has condensed a very complete survey of all the up-to-date knowledge of this very important subject It is based largely upon his own experience but there are numerous references which will facilitate the reading of anyone who wishes to delve further into any particular phase.

It is written in such a way as to be of great interest and definite value to the student, the general practitioner, the general surgeon or the urologist and is heartily recommended to any or all of these groups

N P R

**tioners and Students** By J. J. WALKER, F.R.C.S Octavo of 228 pages, with 80 Skiagraphic plates. New York, William Wood and Company, 1927 Cloth, \$7.00

As the name succinctly states, this book is devoted exclusively to X-ray interpretation with enough of the clinical picture only to evaluate the findings It is written essentially for the student and general practitioner and on many topics serves to whet the appetite for further study

The subject is presented in non-technical yet systematic style and the more important conditions solvable by X-ray are well considered The absence of theory and terseness of thought make the style alluring and interesting

A didactic presentation—excellent for students, is essentially maintained with tabulation of pathological findings

**A PRIMER FOR DIABETIC PATIENTS** A Brief Outline of the Treatment of Diabetes with Diet and Insulin, Including Directions and Charts for the Use of Physicians and Planning Diet Prescriptions By RUSSELL M WILDER, M.D. 3rd Edition, reset 12mo of 134 pages Philadelphia and London, W B Saunders Company, 1927 Cloth, \$1.50

The third edition of this manual has been revised and some of the sections enlarged It is one of the most useful volumes for the use of the patient and saves the physician a good deal of the trouble of instruction.

Perhaps the most interesting part for the physician is that which deals with the planning of diet prescriptions The author believes that the fear of fat has been largely

overcome by the success of the high fat diets of Petren, Newburgh and Marsh and himself Three sample diets are given, the first of 2,000 calories, of carbohydrate 74 grams, protein 50 grams, fat 167 grams and sugar value of 120 grams This has a fatty acid to glucose ratio of  $1\frac{1}{2}$  to 1 The second diet is of 2,250 calories, C 70, P 50, F 196 sugar value 120 and fatty acid to glucose ratio of  $1\frac{1}{2}$  to 1 The third diet of 2,500 calories contains C 68, P 50, F 226, sugar value 120 and has a fatty acid to glucose ratio of  $1\frac{1}{2}$  to 1

High fat diets were being more and more used until insulin came along and made them less necessary When one had a choice between hyperglycemia and glycosuria undernutrition to the point practiced by Allen or a high fat diet along the lines of those of Newburgh and Marsh the last seemed to many the most desirable unless proven dangerous and wrong in principle.

The first diet of Wilder which is moderately high in fat but comes within the ratio of fatty acid to glucose of  $1\frac{1}{2}$  to 1 is probably the type most generally used at the present time

W E McCOLLUM

**THE CONQUEST OF DISEASE.** By THURMAN B RICE A.M., M.D. Octavo of 363 pages, illustrated. New York, The Macmillan Company, 1927 Cloth, \$4.50

Doctor Rice's work is interesting reading to a physician but to a lay person it is thrilling, instructive, and fascinating It fell into the hands of a female member of our family and she said it beat most of the modern best-seller novels She read the book at two sittings.

We began to read it intending to skip through the pages as a stone skims the surface of a pond and found ourselves reading the pages without jumping a paragraph or a word

When we finished we felt repaid for the time spent and voted Dr Rice a sincere expression of thanks and appreciation for being permitted to read his effort. We cannot understand why the firms that syndicate stuff to the newspapers of our land do not get on to such works as *The Conquest of Disease* and offer it to the masses in small doses We are sure it would take and the demand for continuous articles would be insistent.

Quickly—Part I deals with *Ye Good Olde Days* (a gem), *The Scientific Conquest of Transmissible Disease*, *The Cause of Transmissible Disease*, *Infection and Resistance*, and *How We "Catch" Disease*.

Part II deals with *The Transmissible Diseases and Their Prevention*. Subdivision A deals with *Disease Spread by Intestinal Discharges* and B, *Saliva Born Diseases*. C, *The Insect Born Diseases*, D, *Diseases Transmitted to or Through the Skin or Mucous Membranes*, *The Contact Diseases*

Part III—*The Means by Which Transmissible Diseases are Controlled*.

We recommend you buy a copy, read it, then give it to your wife to read, and she'll give it to the other members of the family All will enjoy it It is the type of thing the public should know more about.

T S W

**MANUAL OF OPERATIVE SURGERY.** By SIR HOLBERT J WARING, M.S., M.B. Sixth Edition 12mo of 868 pages, illustrated. London and New York, Oxford University Press [1927] Cloth, \$5.25 (Oxford Medical Publications)

This little manual of Operative Surgery containing eight hundred and fifty-two pages and six hundred and eighteen illustrations is as complete as any small work dealing with this subject could be.

Many types of operative procedure covering every region of the body are included, and described in a brief and thoroughly comprehensive manner

For the surgeon this small volume should prove invaluable for a quick review of an impending operative procedure

R F H

**THE ELEMENTS OF MEDICAL TREATMENT** By ROBERT HUTCHINSON, M.D. 12mo of 163 pages New York, William Wood and Company, 1926 Cloth, \$3.00

This volume of one hundred and sixty pages based upon the author's lectures at the London Hospital on elementary therapeutics and the principles of treatment, contains much useful information carefully prepared and presented. "The book merely aims at setting out principles and their application to the commoner forms of disease met with in practice, special attention being given to the prescription of drugs."

The author gives some general principles in the treatment of disease and then describes briefly, with special consideration and treatment, such conditions as fever, pain, insomnia, heart failure, bronchitis, anemia, hypertension, nephritis, diabetes, endocrine treatment, psychotherapy and some of the so-called minor medical operations as paracentesis, thoracentesis and vivisection.

It seems hardly possible that so much useful, accurate information can be presented in so small a volume. The treatment is not always the same as that followed in different countries but it is good. Many of the useful non-medical procedures in medical treatment are presented here. This is an instructive volume.

HENRY M. MOSES

**DISEASES OF THE HEART Their Diagnosis, Prognosis, and Treatment by Modern Methods** By FREDERICK W. PRICE, M.D. Second Edition Octavo of 534 pages, illustrated London and New York, Oxford University Press [1927] Cloth, \$6.20 (Oxford Medical Publications)

Within the scope of 500 pages Price has presented a condensed consideration of modern cardiology.

The volume is complete and reflects great credit upon the author. He was associated with Mackenzie for several years and the master's views are reflected throughout the book, but Price is definite in his own observations, and the personal pronoun is advantageously used.

The chapters are short, the discussions brief, at times we wish that the author had not denied himself more space, for conciseness can be too concise. References are necessarily scanty.

In outlining the heart preference is expressed for the mediate or indirect method. The direct method and the threshold method are omitted, probably in the interest of simplicity. The polygraph throughout receives true Mackenzian emphasis.

Graham Steell's name is misspelled on page 305, the pen of an Englishman should not slip on the name of this compatriot.

Three fine chapters conclude the book, namely, Anesthesia in Relation to Cardio-vascular Affections, Clinical Electrocardiography, and X-ray Examination. The most representative of 1,500 electrocardiograms were used in illustrating the text and they are particularly well chosen and well printed.

The index is especially thorough for a volume of this size.

FRANK BETHEL CROSS

**THE NATURAL PROCESSES OF HEALING IN PULMONARY TUBERCULOSIS** By MARC JAQUEROD, M.D. Translated by J. DENNY SINCLAIR, M.B., Ch.B. Octavo of 107 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$3.00

This is a short treatise on the pathogenesis of the healing process in Pulmonary Tuberculosis, and while containing nothing but what has been frequently mentioned before, the author stresses certain factors in the process in healing that are well worthy of emphasis. Much has been written in the past on the mechanism of healing by the process of fibrosis and calcification. It is only in

more recent times that attention has been called to the fact that a considerable amount and degree of healing may occur through the simple process of resolution. Dr. Jaquerod writes most convincingly, especially on this latter phase, and supports his reasoning by the display of a number of most excellent roentgenographical reproductions.

We heartily commend this book to all students of Tuberculosis and to all general practitioners of medicine.

FOSTER MURRAY

**A MANUAL OF PHARMACOLOGY AND ITS APPLICATIONS TO THERAPEUTICS AND TOXICOLOGY** By TORALD SOLL-MANN, M.D. Third Edition, entirely reset Octavo of 1,184 pages Philadelphia and London, W. B. Saunders Company [1926] Cloth, \$7.50

This third edition of this well known work has been made to conform with the new Pharmacopoeia and otherwise revised to include more recent conceptions of the pharmacologic actions of the commoner drugs. Sollmann's book has long been an accepted standard on pharmacology, and the present issue maintains the reputation of its predecessors.

As a comprehensive, up-to-date treatise on pharmacologic action of the *Materia Medica*, this work is all that is to be desired.

M. F. De L.

**MEDICAL SCIENCE FOR EVERYDAY USE** By SHIELDS WARREN, A.B., M.D. 12mo of 178 pages Philadelphia, Lea and Febiger [1927] Cloth, \$2.00

This is a revised and rewritten collection of a series of articles which appeared for a number of years in the Sunday edition of a Boston newspaper. Some of the things touched upon are: The Growth of Children, Work and Exercise, Diet and Obesity, Sleep and Sleeplessness, The Way Germs Work, Diabetes, High Blood Pressure, Hay Fever, and Cancer. Such work is midway between the successful and often quite reliable newspaper articles and the scientific text books for the medical student and physician, and such a book unquestionably will do a great deal toward educating the public along modern medical lines, and combating the pernicious propaganda which at the present time is emanating from fiction, thoroughly revised. Re-edited by THOMAS McCRAE, M.D. Assisted by ELMER H. FUNK, M.D. Volume 4. Diseases of the Respiratory System—Diseases of the Circulatory System. Octavo of 1011 pages, illustrated Philadelphia, Lea and Febiger, 1927 Cloth, \$9.00

Volume IV of this edition of *Modern Medicine* is devoted to a consideration of diseases of the respiratory system (except pneumonia and tuberculosis) and diseases of the circulatory system. A proper balance is struck, although the allotment of 200 pages for Maude Abbott's chapter on congenital cardiac disease seems excessive, as only 625 pages are available for the second part of the volume.

There is much material of value presented by the distinguished contributors. The press work is splendid and errors conspicuous by their infrequency. Rackemann is mentioned in stating on page 96 that Balthasar described, while 424 springs are mentioned which were popular water commercially, and 240 springs which were popular resorts half a century ago, but which have fallen into desuetude.

The text is divided into four parts. In the first, on the Classification of Mineral Waters there are given the solid, gaseous content, dosage and physiological action; the second part, Crounotherapy, third, Balneotherapy; and the fourth, Classification of the Mineral Waters of the United States by States.

A work of this kind will do much to enable the physicians of this country to decide whether hydrotherapy is of service to them and to their patients.

W. H. D.

**FOUR THOUSAND YEARS OF PHARMACY** An Outline History of Pharmacy and the Allied Sciences By CHARLES H. LA WALL, Ph.M., Phar.D. Octavo of 665 pages, illustrated Philadelphia and London, J. B. Lippincott Company [1927] Cloth, \$5.00

If we were on a committee to choose a "Book of the Month" for Physicians, we would vote this work of Dr. LaWall's at the head of the list. We suggest every physician own Garrison's History of Medicine and LaWall's Four Thousand Years of Pharmacy.

It is a book of 665 pages with 64 illustrations. It is a book every physician will find rare reading, full of interesting surprises, and sure to increase his culture and appreciation of his medical background.

In the space allotted us we can only offer an outline of the Contents:

Ancient Pharmacy and Its Earliest Side-Line—Medicine. Science in Embryo.

Pharmacy during the Greek, Alexandrian, and Roman Periods. The Kindergarten of Science.

The Arabians Preserve the Pharmaceutic Art and Carry the Torch of Professional and Scientific Knowledge from the 6th to the 13th Centuries.

Medieval Pharmacy and Alchemy from the time of Roger Bacon to the 15th Century.

Pharmacy During the Famous 15th Century. A Century of Alchemistic Frenzy. Beginning of the Renaissance.

The Glorious 16th Century in Pharmacy. The Century of Paracelsus Pharmacy and Science.

The Century of Famous Pharmacopoeias and Notable Characters. The Golden 17th.

The Progressive 18th Century. Pharmacy Ascendant. The Birth of Chemistry. The Beginnings of Modern Science.

The Recent 19th Century. The Development of Pharmacy in America.

The Present 20th Century. Whose History Cannot be Written.

There is a Bibliography, a Chronological Table and 32 pages in the Index.

The illustrations are excellent.

T S W

**X-RAY DIAGNOSIS** A Manual for Surgeons, Practitioners and Students. By J. MAGNUS REDDING, F.R.C.S. Octavo of 228 pages, with 80 Skiagraphic plates. New York, William Wood and Company, 1927. Cloth, \$7.00.

As the name succinctly states, this book is devoted exclusively to X-ray interpretation with enough of the clinical picture only to evaluate the findings. It is written essentially for the student and general practitioner and on many topics serves to whet the appetite for further study.

The subject is presented in non-technical yet systematic style and the more important conditions solvable by X-ray are well considered. The absence of theory and terseness of thought make the style alluring and interesting.

A didactic presentation—excellent for students, is essentially maintained with tabulation of pathological findings, text-book in style.

As with most authors, the older anatomical nomenclature is employed. It is, however, regrettable such confusion exists in naming osseous growths that our English contemporaries employ the term myeloma—to our giant cell tumor. Would that our American Registry of Bone Sarcoma become universal, so that we might all talk one tongue and finally make order out of present chaos.

Indications and limitations of the fluoroscope are well presented and the importance of proper interpretation is well emphasized. Illustrations are profuse and for the most part good.

For those wishing a ready reference, brief and accurate,

it is to be recommended and should therefore find favor with the vast majority of our profession.

MILTON G. WASCH

**DISEASES OF THE INTESTINES** By A. P. CAWADIAS O.B.E., M.D. Octavo of 299 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$6.00.

The writer of this little English work presents his subject in a rather novel way. Instead of the usual lengthy description of the various diseases of the intestines, he has taken as the basis of his study the "Syndrome," which he defines as "a group of symptoms and signs corresponding to a certain deviation of the function of an organ or to a lesion of an organ." The first chapter on the "Medical Anatomy of the Intestines" is a masterpiece of brevity and clearness.

The subsequent chapters are each devoted to discussion of a syndrome, its various causes and appropriate treatments. "The Intestinal Dyspepsias from Inefficiency of Enzyme Action" makes an interesting chapter. "Inflammatory Syndromes" include enterocolitis, typhlo-colitis and sigmoido-proctitis. "Localized Inflammatory Syndromes" include appendicitis, sigmoido-diverticulitis, proctitis typhlitis and colitis. "Motor Syndromes" include organic colon stasis, functional colon stasis, stenosis of small intestine, intestinal obstruction and functional diarrheas. "Vascular Syndromes" include hemorrhoids and arteritis. The last few chapters are devoted to "Special Syndromes" including duodenal ulcer, intestinal cancer and intestinal worms.

While the handling of the subject is interesting, and in some ways may aid in the study of intestinal diseases, yet a few of the subjects treated show either a lack of familiarity with the diseases mentioned or a somewhat antiquated viewpoint. On the whole however, the book can be recommended as a valuable addition to any library on gastro-enterological subjects.

A

**INDEX AND HANDBOOK OF X-RAY THERAPY** By DR. ROBERT LENK. With a foreword by PROF. HOLZKNECHT. Translated by T. I. CANDY, M.B., B.Ch. 12mo of 121 pages. London and New York, Oxford University Press [1926]. Cloth, \$2.25. (Oxford Medical Publications.)

As the name implies, this brochure is a true index covering alphabetically all types of cases amenable to radiotherapy. The first edition was translated into the Italian, Hungarian, Russian and Japanese languages and our thanks are now due to Dr. T. I. Candy for the English translation of the second edition brought up to date.

Dr. Lenk is a product of the Viennese school, associated with the redoubtable Holzknecht whose method of dosage is employed throughout.

The index is compiled essentially for the general practitioner as a guide for those cases most suitable for radiotherapy—the general X-ray reactions one is to look for—a forecast as to the prognosis and suggestions as to the probable duration of the disease and the number of treatments required.

For the specialist formulae of dosage are given in concise form, covering the various diseases, employing the prescription style of Holzknecht.

It is a book which should become increasingly popular, as it offers not only useful advice as to those diseases, the efficacy of X-ray therapy for which is beyond question, but discusses many conditions in which X-rays are now being employed, heretofore not considered at all amenable.

The handbook should be on every practitioner's shelf as a glance will locate the disease sought and concisely state what can be anticipated by the employment of this type of modern radiotherapy.

MILTON G. WASCH

**THE ELEMENTS OF MEDICAL TREATMENT** By ROBERT HUTCHINSON, M.D. 12mo of 163 pages New York, William Wood and Company, 1926 Cloth, \$3.00

This volume of one hundred and sixty pages based upon the author's lectures at the London Hospital on elementary therapeutics and the principles of treatment, contains much useful information carefully prepared and presented. "The book merely aims at setting out principles and their application to the commoner forms of disease met with in practice, special attention being given to the prescription of drugs."

The author gives some general principles in the treatment of disease and then describes briefly, with special consideration and treatment, such conditions as fever, pain, insomnia, heart failure, bronchitis, anemia, hypertension, nephritis, diabetes, endocrine treatment, psychotherapy and some of the so-called minor medical operations as paracentesis, thoracentesis and vivisection.

It seems hardly possible that so much useful, accurate information can be presented in so small a volume. The treatment is not always the same as that followed in different countries but it is good. Many of the useful non-medical procedures in medical treatment are presented here. This is an instructive volume.

HENRY M. MOSES

**DISEASES OF THE HEART Their Diagnosis, Prognosis, and Treatment by Modern Methods** By FREDERICK W. PRICE, M.D. Second Edition, Octavo of 534 pages, illustrated London and New York, Oxford University Press [1927] Cloth, \$6.20 (Oxford Medical Publications)

Within the scope of 500 pages Price has presented a condensed consideration of modern cardiology.

The volume is complete and reflects great credit upon the author. He was associated with Mackenzie for several years and the master's views are reflected throughout the book, but Price is definite in his own observations, and the personal pronoun is advantageously used.

The chapters are short, the discussions brief, at times we wish that the author had not denied himself more space, for conciseness can be too concise. References are necessarily scanty.

In outlining the heart preference is expressed for the mediate or indirect method. The direct method and the threshold method are omitted, probably in the interest of simplicity. The polygraph throughout receives true Mackenzian emphasis.

Graham Steell's name is misspelled on page 305, the pen of an Englishman should not slip on the name of this compatriot.

Three fine chapters conclude the book, namely, Anesthesia in Relation to Cardio-vascular Affections, Clinical Electrocardiography, and X-ray Examination. The most representative of 1,500 electrocardiograms were used in illustrating the text and they are particularly well chosen and well printed.

The index is especially thorough for a volume of this size.

FRANK BETHEL CROSS

**THE NATURAL PROCESSES OF HEALING IN PULMONARY TUBERCULOSIS** By MARC JAQUEROD, M.D. Translated by J. DENNY SINCLAIR, M.B., Ch.B. Octavo of 107 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$3.00

This is a short treatise on the pathogenesis of the healing process in Pulmonary Tuberculosis, and while containing nothing but what has been frequently mentioned before, the author stresses certain factors in the process in healing that are well worthy of emphasis. Much has been written in the past on the mechanism of healing by the process of fibrosis and calcification. It is only in

more recent times that attention has been called to the fact that a considerable amount and degree of healing may occur through the simple process of resolution. Dr. Jaquerod writes most convincingly, especially on this latter phase, and supports his reasoning by the display of a number of most excellent roentgenographical reproductions.

We heartily commend this book to all students of Tuberculosis and to all general practitioners of medicine.

FOSTER MURRAY

**A MANUAL OF PHARMACOLOGY AND ITS APPLICATIONS TO THERAPEUTICS AND TOXICOLOGY** By TORALD SOLL MANN, M.D. Third Edition, entirely reset Octavo of 1,184 pages Philadelphia and London, W. B. Saunders Company [1926] Cloth, \$7.50

This third edition of this well known work has been made to conform with the new Pharmacopoeia and otherwise revised to include more recent conceptions of the pharmacologic actions of the commoner drugs. Sollmann's book has long been an accepted standard on pharmacology, and the present issue maintains the reputation of its predecessors.

As a comprehensive, up-to-date treatise on pharmacologic action of the *Materia Medica*, this work is all that is to be desired.

M. F. De L.

**MEDICAL SCIENCE FOR EVERYDAY USE** By SHIELDS WARREN, A.B., M.D. 12mo of 178 pages Philadelphia, Lea and Febiger [1927] Cloth, \$2.00

This is a revised and rewritten collection of a series of articles which appeared for a number of years in the Sunday edition of a Boston newspaper. Some of the things touched upon are: The Growth of Children, Work and Exercise, Diet and Obesity, Sleep and Sleeplessness, The Way Germs Work, Diabetes, High Blood Pressure, Hay Fever, and Cancer. Such work is midway between the successful and often quite reliable newspaper articles and the scientific text books for the medical student and physician, and such a book unquestionably will do a great deal toward educating the public along modern medical lines, and combating the pernicious propaganda which at the present time is emanating from fiction, thoroughly revised. Re-edited by THOMAS McCRAE, M.D. Assisted by ELMER H. FUNK, M.D. Volume 4. Diseases of the Respiratory System—Diseases of the Circulatory System. Octavo of 1011 pages, illustrated Philadelphia, Lea and Febiger, 1927 Cloth, \$9.00

Volume IV of this edition of *Modern Medicine* is devoted to a consideration of diseases of the respiratory system (except pneumonia and tuberculosis) and diseases of the circulatory system. A proper balance is struck, although the allotment of 200 pages for Maude Abbott's chapter on congenital cardiac disease seems excessive, as only 625 pages are available for the second part of the volume.

There is much material of value presented by the distinguished contributors. The press work is splendid and errors conspicuous by their infrequency. Rackemann is ~~correct in stating on page 96 that Bath-houses~~ described, while 424 springs are mentioned which saw water commercially, and 240 springs which were popular resorts half a century ago, but which have fallen into desuetude.

The text is divided into four parts. In the first, on the Classification of Mineral Waters there are given the solid, gaseous content, dosage and physiological action, the second part, Crounotherapy, third, Balneotherapy, and the fourth, Classification of the Mineral Waters of the United States by States.

A work of this kind will do much to enable the physicians of this country to decide whether hydrotherapy is of service to them and to their patients.

PRESCRIBED BY PHYSICIANS FOR MORE THAN 50 YEARS

for difficult nutrition cases  
... this effective health food  
and digestant!

# Maltine

P L A I N

No APPETITE      weak digestion  
    faulty assimilation      How  
often have you searched for a way to  
impart strength to depleted bodies?

In such cases Maltine may be tried  
This malt extract is a highly nourishing  
food and an agent for the digestion  
of starchy food. It contains vitamins,  
mineral salts, and soluble vegetable  
albuminoids—all valuable in body-  
building. And tests show that it is  
rich in diastase—the active digestive

agent which turns starch into sugar.  
Maltine is the only malt extract  
which combines in concentrated form  
the essential proteid elements of bar-  
ley, wheat and oats. It has a high  
percentage of diastase. It mixes read-  
ily with milk, gruel and similar foods,  
which it renders more palatable. It is  
pure, dependable and inexpensive.

As a nutrient, as a digestant—give  
Maltine. Every druggist has it. The  
standard product of a standard house.

*Rich in diastase*

## APPENDICOSTOMY

The April number of *California and Western Medicine* has a series of brief articles on the irrigation of the large intestine through the appendix. This procedure came up about ten years ago but is now almost discarded—EDITOR'S NOTE

*Dr P K Gilman*—Fixation of the appendix in the abdominal wall and using it as a fistula for irrigation of the colon was first performed by Weir. This comparatively easy operation suffered a not uncommon experience of a new surgical procedure. Enthusiasts, ignorant of or ignoring the mechanical and physical fundamentals of the diseased region to be influenced, popularized appendicostomy. This popularity waned deservedly, the pendulum swinging too far, however, as it had previously swung too far in favor of the operation. While the indications justifying appendicostomy are comparatively rare, I feel that there is still a place for this therapeutic aid.

"Introduced for purposes of lavage of the large bowel and for the introduction of drugs we now know this purpose to be readily accomplished by rectal administration. The X-ray has shown us that fluid injected from below promptly and completely reaches all parts of the large bowel. However, in certain intractable amebic infections of the colon where oral and rectal medication have failed, prompt improvement has followed an appendicostomy and the introduction of medicaments. This improvement may be due to the fact that the drugs reach the lining of the appendix in greater concentration than is possible by rectal administration and thus put a stop to reinfestation of the large bowel from the appendiceal mucosa. Also appendectomy by removing this focus might have in these patients accomplished the same result as it did in others where removal was done instead of appendicostomy. Be that as it may, I believe in carefully selected patients with intractable amebic colitis appendicostomy is not troublesome but easily cared for as the normal direction of peristalsis toward the cecum and the valve-like character of the opening into the bowel prevent escape of cecal contents, while lavage through it is simple enough to permit the patient to carry this out.

"In nonspecific colitis where the object is not lavage but rest of the colon by diversion of the fecal stream, the operation is useless. Similarly the operation fails when performed to allow lavage in chronic constipation. Here

the effect is but temporary and possesses no advantage over properly performed colonic irrigations.

*Dr Rea Smith*—The two indications usually given for appendicostomy are (1) irrigation for medication of the colon, (2) bowel drainage for rest or relief of obstruction.

"It seems to me that there is no sound physiological basis for its performance for medication. The bowel is provided with a mechanism for peristalsis and reverse peristalsis, and if unobstructed, irrigation from the rectum will reach any part of the colon as easily as though the appendicostomy opening.

"The patients who do not clear up after ordinary lavage and which seem to demand appendicostomy for medication of the colon are those with a partial obstruction in the ascending colon and a dilated, toneless cecum. If surgery is indicated, to my mind it should be directed toward the relief of the obstruction and restoration of the normal peristaltic waves, rather than opening the appendix. The tying of the cecum to the anterior wall by appendicostomy in itself interferes with the bowel's emptying and tends to produce a cecal stasis, so that after the appendicostomy has closed the patient is very likely to carry during the rest of his life a crippled cecum which fails to empty properly.

"Cecostomy, in my opinion, is a much better operation than appendicostomy for the purpose of bowel drainage in instances of complete obstruction lower down, especially as a preparatory measure for a radical removal of the obstruction after relief of toxemia.

"In short, I believe that appendicostomy for medication is an unnecessary procedure likely to be followed by rather serious complications, and that cecostomy is a better and surer operation for bowel drainage when that is indicated, so that I can see no surgical indication for its performance.

*Dr Harrison W Jones*—Every operation performed should bring satisfaction to both surgeon and patient. I have had a reasonably large experience with operative drainage of the intestinal tract and have used appendicostomy for both medication and drainage. The medical patient was one of amebic infection that had resisted all forms of medication by oral administration. I decided to fix the appendix in the abdominal wall, open it and thus

### PALEO-PATHOLOGY

The May issue of *Colorado Medicine* contains the following editorial on pathology in ancient men and animals—EDITOR'S NOTE

"Dr F B Young of Gering, Neb, gave an interesting illustrated lecture before the medical and dental societies of Denver, April 7th. He discussed the pathology existing in prehistoric and extinct animal life. His studies have for obvious reasons been limited to osseous structures. He is able to demonstrate lesions simulating fractures, callus formation, non-union, ankylosis, myositis ossificans, osteosarcoma, osteomyelitis and pyorrhea.

"Such findings will doubtless contribute little if anything to the advance in the treatment of bone lesions. To the student of physiology and pathological physiology it is a profoundly interesting fact that animal life was beset with similar accidents and diseases and was apparently dependent upon the same mechanism of repair as has become so well understood in recent years. Conditions of recovery and certain well-known aids have been added and improved but the impulse to get well is eons old. Such considerations are as humbling to our conceit as they are consoling to our shortcomings. According to this story written in

administer medicine and irrigation directly. This treatment was continued religiously for three months with no apparent results. As a last resort I did an appendectomy and followed with oral medication which brought about a permanent cure at the end of four months.

“My patients in whom appendicostomy or cecostomy was performed for obstruction are twenty-six. In five the appendicostomy was done for the purpose of drainage. None of them drained properly, and I had to resort to cecostomy in order to get sufficient drainage that my patient might make sufficient progress to make him at least a fair risk for a radical operation. In the remainder I did a cecostomy and have abandoned appendicostomy entirely and have been highly pleased with the procedure.

“Dr. H. H. Searls—The operation of appendicostomy is rarely indicated. A search of the records of the University of California Hospital shows but one patient on whom it was performed. A native of Tahiti, suffering from an aggravated and obstinate amebic dysentery, after many weeks of medical treatment, finally only gained relief following appendicostomy by Doctor Terry. Irrigation with quinin bisulphate and later with dilute thymol through the fistula thus established was followed by arrest of the severe dysentery and a corresponding improvement in the patient's general condition.

“The modern trend of surgery, however, is away from the once popular operation of appendicostomy, cecostomy, permitting the introduction of a larger tube, being used in place of it, both for medication of the large bowel and for relief of low obstruction. For the latter condition appendicostomy is nearly always a failure. In such a condition as that found in the patient above cited I feel that appendicostomy is justifiable and indeed proved its value. It has one point in its favor over cecostomy in that termination of the fistulous tract by appendectomy is far easier than the closure of the cecostomy opening.”

### THE HEART'S SONG

The May issue of the *Rhode Island Medical Journal* contains the following poem by a physician author who modestly withholds his name—  
THE EDITOR

Systole-diastole the whole day through  
In a never-ending sequence  
While you live by what you do,  
With your life blood passing through me  
In a cadence like a song,  
Systole-diastole the whole day long.

## THE ATYPICAL FORM OF NEUROFIBROMA\*

Its Differential Diagnosis from Other New Growths of the Skin

By OSCAR L. LEVIN, M.D., and JESSE A. TOLMACH, M.D., NEW YORK, N. Y.

### Introduction

FOR many years the utmost chaos has existed regarding all forms of fibrous tumors and overgrowths of the skin. Even at present, with our numerous detailed descriptions, classifications and subdivisions, numbers of tumors of the skin are diagnosed clinically, either as simple fibroma cutis, or, if multiple, are immediately shunted into that convenient group, Von Recklinghausen's disease, or else, are stamped sarcomas of various types and dealt with accordingly. However, within recent years, it has not been unusual, in our experience, to see the wind taken out of a positive clinical diagnosis, by the pathologist's findings.

It is our purpose, in this paper, to call attention to a form of neurofibroma which clinically resembles various other tumors of the skin, which, because of such close resemblance has been presented before societies with a clinical diagnosis of Kaposi's sarcoma, syphilis, sarcoid, mycosis fungoides, and even papulonecrotic tuberculids, and which have been given a final conclusive diagnosis of neurofibroma by the pathologists. We wish to emphasize the fact that this form of skin tumor is fairly common, but is frequently incorrectly diagnosed clinically. Further, that this form of neurofibroma is not as a rule associated with fibroma molluscum, that it is not accompanied by any of the internal symptoms and disorders of Von Recklinghausen's disease, and finally, that it also differs somewhat from Unna's fibroma simplex, which is the same condition described by Arning and Lewandowski as noduli cutanei.

It is fitting, at this point, before discussing this type of neurofibroma, which we wish to bring to the fore, to focus our attention briefly on the historical development of the recognition and classification of cutaneous nerve tumors, touching upon the various theories of their origin, in order to throw into relief this group of atypical neurofibromas which is frequently misdiagnosed.

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927.

### History and Comments

As far back as 1803 the term "neuroma" was applied to overgrowths of nerve tissue by Odier<sup>1</sup>, to designate "all tumors formed by diseased overgrowth of nerves."

Smith<sup>2</sup> in 1849 classified the tumors according to his conception of their origin, grouping them as (1) those which were of "spontaneous origin," and (2) those which resulted from trauma of the nerves, including those arising from cut-nerve ends.

Like Wood<sup>3</sup>, he believed that nerve tumors—neuromata—originated from the connective tissue sheaths of the nerve, rather than from the nerve tissue itself. As a matter of fact Smith did not believe that a tumor of the nerve tissue itself ever existed, and merely used the term *neuroma* conveniently, in a clinical sense, to designate the origin of the tumor, regardless of its structure.

Virchow<sup>4</sup> was among the first to go about it more scientifically, classifying these tumors on a structural basis, rather than clinical. It was he who divided these neuromas of Wood and Smith into two classes:

(1) True Neuroma (*neuroma verum*), namely a tumor whose essential make-up is newly formed nerve tissue.

(2) False Neuroma (*pseudo-neuroma*), namely, a tumor whose origin is the connective tissue derived from the sheaths of the nerve.

He then sub-classified his true neuromas into three groups:

1—Those containing newly formed nerve cells (*Neuroma ganglio-cellulare*).

2—Those containing chiefly non-medullated nerves (*Neuroma fibrillare amylcinicum*).

3—Those containing medullated nerves (*Neuroma fibrillare myelcinicum*).

And, Virchow maintained that the class of tumors described as neurofibromas were really true neuromas of the second group, suggesting that the non-medullated fibers were, because of lack of proper preparation of the slide, too often interpreted as connective tissue fibers. In other words,

get somebody to cover it. As a rule when you have a subject it isn't hard to get somebody to fit the subject. Big men generally are willing to come and cover the subject if you have the time and the place for it.

Concerning county society bulletins, Dr Knapp said

"As far as bulletins go, I believe that that is quite important. I think something should be said in every bulletin about attendance. The average doctor doesn't care much, he just comes to the meetings most of the time and tries to tell those who are there why he doesn't come oftener. It seems to me that in a bulletin you can publish and keep a record of the attendance of every member during the year. We do. I have a schedule and I can tell every man whether he has been there 100 per cent during the year or not. I have made up a form, a sort of a class record of every man's attendance in the Society."

The activities of the Women's Auxiliaries were presented by Dr Caroline B Crane, who enumerated the following activities of the Auxiliary

- 1 Listing topics of popular interest on society programs
- 2 Cooperation with Parent-Teacher Associations and other lay societies
- 3 Popular meetings for discussing health topics
- 4 Promoting sanitary work such as pure water supplies and clean-up weeks
- 5 Promoting hygiene
- 6 Social service in schools
- 7 Promotion of sociability among the families of doctors

Dr C F DeVries of Lansing told of the cooperation of the Undertakers of Lansing in securing autopsies and helping to perform them. He also described a credit bureau run by doctors, for collecting bills for 15 per cent commission.

Dr George Curry of Flint described the standard work of committees of a county society.

Other topics that were discussed were monthly reports of secretaries, minimum programs for a year's activity, legislation, the annual meeting, the educational endowment Foundation by voluntary gifts, county clinics, listing surgical clinics, medical defense and the Journal.

At the close of the conference the secretaries organized a secretaries association.

examined for these findings. It is generally assumed, however, that the victims of fibromatosis are the subjects of a congenital malformation of the ectoderm, which under a great variety of exciting causes, may slowly or rapidly develop one or more of the manifestations of the disease.

### *Theories of Origin*

The exact nature of the cells involved in neurofibromas is not easily determined and probably not uniform. In a consideration of the histology of nerve tumors, it is far more difficult to arrive at a proper classification, owing to the complex structure of the nerve trunks, and the uncertainty of the source of supporting cells which accompany nerve-fibers, such as the cells of the sheath of Schwann, the neurilemma, the endoneurium, and the lymph sheaths of nerve trunks, all of which, or any of which, may participate in the tumor growth.

For instance, in one general group, commonly classed with the fibromas, the growth affects the connective tissue structures of the nerve, epineurium, perineurium and endoneurium, the specialized nerve elements undergoing atrophy and the tumors appearing fibrous in character.

In another group, the neuromas of Virchow, for instance, there is extensive overgrowth of specialized nerve structure, axis cylinders and myelin sheaths.

In many cases, however, especially in the more actively progressive ones, there is an overgrowth of both nervous and supporting elements, difficult to trace in the tumors, but a complex pathogenesis must be admitted.

All these considerations indicate that neurofibromatosis in all its forms is essentially one and the same disease, and that the underlying factor is a disturbance in the relations between the fetal ectoderm and the tissues which it innervates. In most of the cases it is the motor and sensory nerves which are involved, in some—to what extent is not yet clear—the sympathetic system is involved.

A classification of fibrous tumors of the nerve trunks and filaments based on their histopathology divides them into two main forms:

(1) Cutaneous neurofibromas, multiple and single. To this class belong the fibroma molluscum of Von Recklinghausen, and also the fibroma durum, in which group the atypical neurofibromas which we shall discuss probably belong.

(2) Neurofibromas of the subcutaneous and deeper nerve trunks, in which belong the plexiform neurofibromas, visceral neurofibromas, and neuro-fibrosarcomas.

For our purpose, we need only consider the histopathology of the first group—the cutaneous neurofibromas.

According to Ewing<sup>7</sup>, fibromas are tumors composed chiefly of connective tissue, while neurofibromas are those tumors which may show atrophic nerve fibres.

Von Recklinghausen ascribes the origin of the tumor to the endoneurium of the nerve trunks of the subcutaneous tissue, spreading from there along the nerves, vessels and follicles, toward the epidermis, where it divides into fine bundles. Section of the tumor shows a spongy, ill-defined, glassy substance, exhibiting a grayish translucent appearance. The blood content is usually slight and secondary changes yield corresponding alterations in texture. Multiplicity is a striking feature of neurofibroma. The structure varies greatly, but it commonly presents fibroblasts, fibrils, blood and lymph vessels. The soft tumors contain a considerable portion of cells lying in a soft matrix which is often oedematous. There may be much vascularity which reduces the consistence. The hard tumors contain fewer cells, and secondary changes may occur in the matrix such as hyalin transformation, edema, necrosis, calcification, and mucoid degeneration. The chromatin is increased and the tissue has a neoplastic character. The cells may be large throughout, or active only at the periphery. The arrangement, however, is uniform and is determined by pressure or by the presence of structures, such as blood vessels or nerve trunks, or gland alveoli. The growth is composed of gelatinous connective tissue, the small tumors showing fine fibers and the large ones coarser fibers. There is usually a gelatinous consistency in the centre, showing many spindle-shaped cells and round connective tissue cells with definite nuclei. Frequently, a prominent feature, as pointed out by Unna, is the presence of a large mast-cell, in a reddish ring, made up of spongoplasm, and staining like mast-cell granules. The fibers are gathered into bundles, or what is more unique, show a peculiar arrangement of whorls and ribbon-like strands, an arrangement which is particularly common in tumors associated with the sheaths of nerves. The nerve fibers, as Von Recklinghausen and Kriege have recognized, are neither increased nor diminished in neurofibromas. They are as a whole unchanged and only pressed asunder, or crowded together into these whorls.

The epidermis shows little or no change, except when atrophy is present, due to the pressure of the tumor. Where the regular cystic degeneration of the hair follicles in the center of the tumor has been described by some authors, the probabilities were that they were not dealing with neurofibromas but rather with polypoid naevi or some other form of fibromas.

In larger growths, the cells of the sheath of Schwann and of the endoneurium multiply. Concentric groups of cells, so characteristic of this tumor, have been interpreted as endothelium of the nerve sheaths. In the ganglionic lesions, the

Virchow believed that true neuromas were of greater frequency than generally thought, because he considered neurofibromas true neuromas. However, since 1863, with our improved methods of microscopic study, further observations seem to disprove Virchow's contention. It would appear, judging from more recent studies, that the existence of true neuromas is extremely rare, in comparison with the frequent occurrence of false neuromas, to which group we now know, neurofibromas belong.

Subsequent to Virchow's work on general classification, came the description by Verneuil and Bruns of the plexiform neuromas, a group, which although entirely similar in structure, origin and pathology to the generalized neurofibromas, is rather the result of a more localized overgrowth usually following the distribution of a certain nerve or nerve plexus.

Then, in 1882, came the remarkable piece of work by Von Recklinghausen, who as we all know, was the first to demonstrate the nerve element in certain skin tumors—fibroma molluscum—proving that generalized neurofibromas of the skin were essentially, but not necessarily, associated with connective tissue hypertrophy of the nerve trunks. He also disclosed their frequent association with excessive pigmentation of the skin, the presence of other pigmented lesions like moles, and their occurrence, very often, in individuals of low mentality, who show other disorders, skeletal, psychic, nervous and trophic. Since 1882, we have seen that the generalized neurofibromas of Von Recklinghausen, in varied clinical forms, constitute one of the largest groups of diffuse connective tissue overgrowths of nerve origin, appearing on the skin.

Since Von Recklinghausen, we have the following classification from Thomson<sup>5</sup>

- 1 Multiple neurofibromata—Generalized neurofibromatosis
- 2 Plexiform neurofibromata—Plexiform neurofibromatosis
- 3 Molluscum fibrosum—Cutaneous neurofibromatosis
- 4 Elephantiasis neuromatosa
- 5 Pigmentation of skin associated with neurofibromata (forme fruste)
- 6 "Secondary malignant neuroma," being the sarcomatous transformation of one from or other of neurofibromatosis

The name Von Recklinghausen's disease has been conveniently used to designate the occurrence of these lesions in any of the mentioned forms, whether they occur separately or combined.

We are all, surely, familiar with the clinical appearance of typical neurofibromas of the skin.

The neurofibromas of Von Recklinghausen almost always appear multiple, are rarely regionally limited, usually universal, and are sometimes

accompanied by plexiform neuromas of the cutaneous nerves and nerve trunks. They usually develop in dark-complexioned individuals and may appear in childhood, at the age of puberty, or later in life. In the early stages, and sometimes throughout life, the lesions may be only slightly elevated and not prominent. New ones may appear from time to time and the number varies from a few to several hundred or even thousands. They are irregularly distributed over the body, appearing profusely on the breasts, abdomen, trunk and less numerous on the scalp, neck, face and extremities. They appear as nodules and pedunculated tumors, covered by smooth, intact skin. They may have broad or spherical bases, usually being dome-shaped, and are of soft, doughy consistency. Some may be firm and hard, but most of them are soft, and may show semi-firm nipple-like formations with a summit similar in appearance to a vesicle. The soft tumors which may be depressed, give to the palpating finger the sensation of a hernial ring in the skin. In some the depressions seem to be filled with sebaceous secretion, which may be simply due to myxomatous degeneration.

The tumors vary in color from white to tan, brown, purplish and red. They are of an elliptical or fusiform shape and are usually freely movable, transversely, but not longitudinally. Over the entire body, but particularly on the skin of covered parts, as of the trunk and abdomen, numerous small and large pigmented macules may be present.

As has been said before, these neurofibromas of Von Recklinghausen appear together with other symptoms. Nervous disturbances, including pain, anesthesia, defects of special senses, neurones, epilepsy, mental disorders, idiocy, fragility of the bones, infantilism and malformations, all pointing to general and especially nervous deficiency. Various digestive disturbances, jaundice, urobilinuria, and alterations of nitrogenous metabolism have been cited in support of the theory of general dyscrasia.

The congenital and slightly hereditary character is prominent in all forms of fibromatosis, suggesting the existence of abnormal qualities in the connective tissues of these subjects.

For general fibromatosis various theories of origin have been assumed, such as the theory of recurrent or chronic infection, as suggested by the recurrent inflammatory processes in elephantiasis and its resemblance to leprosy. The theory of auto-intoxication is suggested by many constitutional symptoms and especially by certain cases resembling Addison's disease. Pregnancy, alcoholism and over-use of arsenic have been reported as exciting causes. In the author's (O. L.) paper<sup>6</sup> on the subject, published several years ago, he called attention to the fact that the great majority of cases showed definite signs of endocrine-vegetative disorders, if they were carefully

frequently on the extremities and buttocks, showing no tendency to enlarge or undergo radical change in any way, except possibly for some slight atrophy in some lesions. They are usually insensitive, painless and are never associated with any internal disorders or mental disturbances. Some of the tumors show a tendency to spontaneous involution.

### Report of Cases

The following five cases which demonstrate clearly this atypical form of neurofibroma were selected at random from the number of cases which we have observed and recorded in the last few years.

*Case No 1*—In this instance, the tumor formation in its main clinical features presented a picture so suggestive of Sarcoid of Boeck, that the clinical diagnosis of neurofibromas was made with much misgiving.

The patient, Mrs C B, American, married, housewife, aged 36, had been attending the Skin Clinic of the Cornell University Medical College. She had noticed the slow, gradual, progressive development of a tumor over the shoulder blade for a period of eleven years, and claimed that it had first appeared after a bruise of the shoulder. Examination revealed an irregularly-rounded growth of the skin, in the right scapular region. It was of a brownish-red color, larger in size than a ten-cent piece. The top of the growth was slightly depressed and flattened, showing some adherent dry scales. It was sharply circumscribed from the surrounding tissues, and the skin over it could not be moved. It felt firm on palpation, and evinced no tenderness on pressure. Situated just above this main lesion were two closely set-together, pea-sized, dark red papules with a faint yellowish tint. Firm pressure with a glass slide on the smaller lesions caused a removal of the red color, and set off the yellow color more prominently.

This patient was presented at a regular meeting of the Manhattan Dermatological Society in March, 1926, with a diagnosis of *Neurofibroma Resembling Sarcoid of Boeck*.

Tissue from the main lesions was examined by Dr James Ewing, Professor in the Department of Pathology at the Cornell University Medical College and Clinic, as well as by Dr John Frank Fraser, pathologist of the Department of Dermatology and Syphilis. The report was neurofibroma.

Dr J Globus, Neuropathologist at the Mount Sinai Hospital, was kind enough to examine and report on the histological findings, and his statement is as follows: "Circumscribed nodule of an uniform histological appearance. The cells are fusiform in character with deeply staining nuclei, arranged in whorls or in long ribbon-like formations. Here and there are seen blood vessels or glandular structures, in the form of ducts lined

by colloidal epithelium. Occasional pigment cells are present. Indications are that the cells are very likely derived from the Schwann membrane cells of the peripheral nerves. The appearance is that of what we know as neurofibroma."

The histopathologic evidence in all the five cases is more or less the same, and is characteristic in each instance of neurofibroma.

### Pathology

Examination under low power of a piece of tissue stained with hematoxylin and eosin revealed the epidermis somewhat compressed and the corium showing a dense, uniform, cellular infiltration. The epidermis as a whole had retained its various layers, but gave one the impression that it had been drawn out or distended by pressure from below. It may be said that though the rete pegs had been retained, yet in some places they were flattened, thus obliterating the papillary bodies in these spots. The striking characteristic observed in the corium was the presence of the circumscribed, dense, cellular infiltration which extended up almost to the papillary bodies and down to the subcutaneous tissue, becoming less marked as it reached further down. Some cellular infiltration into the papillary bodies and some invasion into the subcutaneous tissue could be observed. The collagen which stained less faintly than normal, could be made out in the form of a narrow band above the denser infiltration and the papillary bodies. The cells were separated and enclosed in a fibrous stroma, which looked pale and spongy. The blood vessels in the cutis were numerous, and in places although widely opened, seemed somewhat compressed by the surrounding tissues. Scattered through the tumor there were numerous discrete and aggregated fat cells, forming large clear spaces. The coil glands were evident here and there through the deeper parts of the tumor and seemed to be compressed in some places while in other parts the coils seemed to be unfolded. The sebaceous glands were not prominent and were difficult to find. Scattered through the infiltration were some small, brownish, pigmented areas. An interesting feature observed was the tendency of the cells to arrange themselves in clusters forming elongated ribbons or streaks, or whorls. The fibrillar structure also assumed this characteristic arrangement.

High power examination disclosed a general thinning of all the layers of the epidermis. There was a hyperkeratosis and slight scaling or separation of upper layer of stratum corneum cells. The stratum granulosum was poorly defined, while the cells of the rete were not as regular as normal and more flattened. There seemed to be, in places, an increased oedema with breaking down of some cells of the rete. There was an apparent upward pressure which resulted in a flattening and obliteration of the rete pegs, while in other spots the latter were well formed. The corium

endothelium of the capsules of the ganglion cells multiplies actively. In fact all the elements of the nerve filament or nerve trunk, except the ganglion cells and nerve fibrils participate in the tumor process.

According to Verocay's conception, the tissue of neurofibromas is not connective, but consists of nerve cells or their embryonal equivalents, which have not been properly employed in the development of the nervous system. The validity of this view depends on the nature of the cells of the sheath of Schwann. If these are specialized nerve or glia cells, Verocay's interpretation would seem acceptable. However, from the arrangement of the Schwann nuclei about the nerve fibres it was concluded that the Schwann cells play a primary role in the origin of the tumor.

Heller<sup>8</sup> supported the theory of Von Recklinghausen that these tumors result from sheaths of medullated nerve fibres, after he stained specimens in his own way with modified osmic acid stain. He also observed that the elastic fibres were present in the form of isolated fibrils, fading into the surrounding tissue, which is not in agreement with Unna's observation that the new growth shows no elastic fibers.

#### *The Atypical Neurofibromas— Clinical Appearance*

Coming now to the atypical form of neurofibroma which, after several years' close observation have been identified and distinguished clinically from other tumors of the skin, we must emphasize the fact that because they so closely simulate other cutaneous tumors in appearance, the details of their clinical description must be borne well in mind in order to establish a correct differential clinical diagnosis.

The most frequent sites involved, unlike the generalized molluscum fibrosum of Von Recklinghausen which occurs most frequently on the trunk and abdomen, are the extensor surfaces of the lower extremities, upper extremities, buttocks and scapular regions. On the lower extremities the lesions are seen most often on the front of the legs, less frequently on the buttocks, and front of thighs, and rarely on the feet. A few have been observed over the tendon of Achilles. Involvement of the plantar surfaces as well as the palms has not been observed.

On the upper extremities they appear most often on the extensor surfaces of the forearm, just below the elbows and on the back of the arms. The scapular regions may become involved.

The lesions are rarely observed on the trunk, but in a few instances some have appeared on the abdomen, usually between the umbilicus and pubic region. As for duration, some of the patients stated that they have observed the growths for several years, at least three or four, whereas

others dated their presence as far back as memory could recall. The general statement of the patients as to the progress of the lesions was to the effect that there seemed to be no noticeable tendency to growth or enlargement. They remain stationary, seeming to persist as when first observed. Some, however, show a tendency to become flatter and proceed to atrophy. There is no doubt that some lesions disappear spontaneously, a fact corroborated by the disappearance of some lesions in a patient under observation. This occurrence may correspond to a feature observed by Brickner<sup>9</sup> in a cases of Von Recklinghausen's Disease, where the lesions came and went with pregnancy.

An interesting feature of these atypical neurofibromas is that they occur without any contributing or associated symptoms, and seem to have no etiological explanation. In almost every case the patients made no complaints of pain, tenderness nor physical discomfort of any sort, and no internal disorders could be found. Often the lesions were discovered by the physician in the course of a routine general examination, or, a patient was led to investigate the nature of the growths by the usual layman's fear of malignancy in any growth.

The color of the tumors varies from a pinkish to a dark red or brownish red color. They may also be purplish or bluish red. Some of them show an admixture of yellow within the main lesion. These may represent material from the sebaceous glands, or possibly some fatty degeneration. The tumors are of various sizes, averaging that of a large bean or hazelnut. However, they may be observed as small as a lentil or as large as a walnut. They usually occur singly, or only few in number, although in a female mulatto they were seen in greater numbers—as many as three dozen.

The growths are firm or hard—never soft—but sometimes where atrophy has occurred, they may appear to be of a firm but doughy consistency. Ulceration, however, has never been observed. As a rule the tumors are discrete, but at times they appear to be grouped and may be confused with multiple gummas. They are round, and sharply circumscribed from the surrounding tissue. They may be very slightly movable, or fairly well attached to the deeper structures, and are, as a rule, attached to the overlying skin. The surfaces are smooth and some of the larger lesions show a tendency to flattening, the summits appearing slightly depressed where atrophy has taken place. The lesions feel dry, and may be slightly scaly and itchy.

Summarily, the distinguishing clinical features of these atypical neurofibromas lie in these points—that they are firm, hard, semi-globular tumors, usually of a dark red, purplish or brownish red color, sometimes tinged with yellow, sharply defined from the surrounding skin, more or less firmly attached to the deeper tissues, occur most

negress, who revealed no clinical evidence of any constitutional disease, upon careful physical examination. Search was made especially for tuberculosis. The Wassermann test of the blood was negative.

Examination of the skin revealed about two dozen solid elevated lesions, and some slightly depressed scars on the front of both legs. Distributed over the tibial aspects from just above the ankle to below the knees there were elevated, lentil to pea-sized, dark red, conical, smooth, hard, slightly movable papules. Interspersed among these several flat and slightly depressed soft scars of a fading red color were observed.

The impression gained by those who observed her was that the patient was suffering from papulo-necrotic tuberculids, because of the presence of the hard papules which apparently were going on to necrosis and scar formation.

However, upon removal of a papule, and examination of the tissue by Dr. James Ewing, a diagnosis of neurofibroma was reported.

Analysis of this case demonstrates the fact that the diagnosis of neurofibroma should be kept in mind when lesions of this clinical appearance are encountered. There is no doubt now that the solid lesions went on to atrophy and the formation of pitted scars, rather than to necrosis and scar formation as in tuberculids.

*Case No. 4*—This patient, a male, aged 49, married, a native of Austria and a butcher by occupation, complained of several growths on the buttocks, which had been present since boyhood. There were no subjective symptoms referable to the tumors, and they had not grown since they reached their present size some years previously, but he had been referred to the Skin Clinic from the Medical Department of the Cornell University Medical College Clinic for an opinion as to the possible nature of the lesions. He had applied for treatment of asthma, in the medical clinic.

Examination of the skin revealed several tumors on both buttocks. These were purplish and bluish-red in color, elevated, rounded, and varied in size from that of a bean to a hazel-nut. The lesions were firm and hard. Although generally rounded, the larger growths showed slightly depressed and atrophic flattened tops, and all the lesions were grouped on the buttocks. The smaller ones showed some scaling. There was no pain nor tenderness.

Provisional diagnoses of sarcoids, sarcomas and gummas had been offered by several dermatologists, but we made a clinical diagnosis of neurofibromas which was confirmed by Dr. James Ewing, upon examination of the tissue which had been excised.

*Case No. 5*—J. G., male, white, aged 39, Russian, and a clothing operator by occupation, came for a consultation in October 1926. He complained of the presence of several growths on both buttocks and thighs. These lesions had been present, he stated, since childhood but he had

never suffered any pain nor discomfort as a result of them. He was merely curious to know their nature.

Examination disclosed the presence, on the buttocks and extensor surfaces of the thighs, of several very hard, pea to grape-sized, elevated tumors, with flattened tops and large bases. Some of the tumors were slightly bluish, some a reddish blue, and a few were of the color of the surrounding normal skin. They were not tender upon pressure. The rest of the skin was apparently normal. Clinically the case suggested either sarcoids or neurofibromas.

A routine physical examination failed to reveal any apparent abnormalities of the heart, lungs, abdomen or nervous system. The blood Wassermann test was negative, as was also the blood count and urine analysis.

A section was made from one of the tumors and the report made by both Dr. James Ewing and Dr. John Frank Fraser was that of neurofibroma.

### *Differential Diagnosis*

In discussing the differential diagnosis of these atypical neurofibromas from the other cutaneous growths to which they bear a close clinical resemblance, it becomes necessary to consider the fibroma simplex of Unna,<sup>10</sup> which is identical with the noduli cutanei of Arning and Lewandowski,<sup>11</sup> Von Recklinghausen's Disease, neuroma, keloid, Kaposi's sarcoma, tuberculosis, gumma, mycosis fungoides, leukemia, xanthoma tuberosum multiplex, myoma, lipoma and sebaceous cyst.

The etiological explanation of the fibroma simplex of Unna and noduli cutanei of Arning and Lewandowski immediately sets them apart from the atypical neurofibromas, since both Arning and Unna definitely ascribe them to the results of trauma, as from insect bites, or to a development around foreign bodies, like splinters. Arning, moreover, observed that they usually follow itchy skin eruptions such as lichen planus, or neurodermite, where foreign bodies have entered the skin through excoriations. It would also seem, according to his observation, that those individuals who seem predisposed to the development of the nodules, show a keloid tendency. No such etiological factors seem to play a part in the atypical neurofibromas, which seem to arise through no definite cause.

However, because the fibroma simplex and nodule cutanei bear such a close resemblance clinically to the appearance of the atypical neurofibromas, including a similarity in consistency, duration, location, color, number and configuration, a conclusive differential diagnosis must depend almost entirely upon the histological aspect.

As a matter of fact, since the histopathology varies mainly in the fact that the fibroma simplex and noduli cutanei showed no neural elements, and, since it is probable that the great majority of fibromas and fibrosarcomas of the skin and

showed the collagenous fibres to be poorly stained and very much obscured by the very abundant numbers of cells which were fusiform. There were also some elliptical cells, some round cells and occasionally some narrow, flattened cells, which showed prolongations from their ends, suggesting the appearance of fibrils. The cells were arranged in strand-like formations and in whorls, as seen under the low power lens.

The rest of the corium was made up of very fine, poorly staining, wavy fibrils which when seen en masse gave a spongy aspect to the tissue.

Numerous blood vessels which appeared compressed were scattered throughout the corium. The changes observed in coil glands were also evident as under the low power lens, and there seemed to be a proliferation of the lining cells. Particles of brownish pigment could be seen here and there throughout the corium, and in the deeper part of the epidermis.

Several of the sections showed an accumulation of fat cells in the corium, which would appear to indicate that the yellowish spots observed in some of the tumors represented areas of fat degeneration.

This characteristic histopathologic picture of neurofibroma was found in the sections of all the cases, with but slight variance. It is therefore deemed unnecessary to give a reading of the slides in the following cases.

*Case No. 2*—The patient, H. D., was a married, female adult, aged 37, who appeared at the Beth Israel Dispensary in 1920. She stated that she had observed growths of the upper extremities for more than six years. Prior to her admission to the clinic a clinical diagnosis of tertiary syphilis had been made because of the grouped and segmental configuration of the solid, hard lesions. The Wassermann test of the blood had been negative on several occasions.

A group of solid, hard, red growths had first appeared on the outer surface of the right forearm, just below the elbow. No history of trauma, chemical or other form of irritation could be obtained by way of possible etiological factors. The patient had had four healthy children and there was no history obtainable indicative of syphilis.

During a period of six years new tumors had appeared on both the right and left forearms and these, after growing slowly, finally remained stationary. However, she stated that some of the lesions seemed to be getting smaller. This proved to be true for while under observation some of the lesions became smaller and even faded away with slight atrophy. There were no local subjective symptoms like discomfort, itching or pain, and no general symptoms referable to the disorders of the nervous system could be discovered.

Both forearms on the extensor surfaces presented pea-sized, bean-sized, dark red, brownish and bluish, circumscribed, elevated, rounded nodules, which felt firm and hard. On the left forearm, near the elbow, there was a brownish-red, large

pea-sized, rounded, hard, deeply infiltrating, slightly movable nodule. On the lower one-third of this aspect of the forearm, there were a group of similar, but smaller lesions. On the extensor surface of the right forearm, near the elbow, there were several similar pea-to bean-sized nodules, which were aggregated to form a mass, serpigenous in outline. These lesions were hard and showed no tendency to softening and ulceration. Because of this peculiar configuration, a possible diagnosis of syphilis was considered, and the blood was examined for the Wassermann test which was found to be negative.

A nodule was removed and examined for its pathology, and to our surprise, a diagnosis of neurofibroma was made by Dr. Eli Moschikowitz, the pathologist at the hospital.

The patient was treated by means of various local saline applications, but after several weeks' attendance, she ceased visiting the clinic. In 1922, she returned and showed the lesions as when first seen, but those on the right forearm were less prominent, flatter, paler and some had disappeared, leaving slight atrophy of the skin. She had used a mercury ointment and it was deemed advisable to repeat the Wassermann test to again exclude the possibility of syphilis. The Wassermann test again was negative.

When this case was presented before a meeting of the Section of Dermatology of the New York Academy of Medicine, it was doubted whether neurofibromas could disappear spontaneously. Since then a study of the literature revealed the fact that spontaneous cures have been observed in neurofibromas. There are cases on record demonstrating the fact that neurofibromas may disappear under certain local or general conditions, and reappear later.<sup>9</sup>

This case demonstrates readily the fact that there are tumors of the skin which in their clinical appearance may resemble tertiary syphilis, and on histological study show the structure of neurofibroma, that they may show spontaneous involution, and, that they may occur without any other evidences of local or general disturbances as in Von Recklinghausen's disease.

*Case No. 3*—A most interesting case was that which was observed in a female mulatto, where the lesions on the legs suggested the appearance of papulo-necrotic tuberculi.

The patient was a female mulatto, aged 29, married, and a native of this country. She complained of numerous growths on the front of both legs, which had been appearing over a period of four years. Numerous small hard growths had insidiously appeared and gradually increased in number. These would reach the size of a pea and remain stationary, while some of them seemed to fade slowly, leaving scars. At no time had ulcers been present, neither was any pain nor tenderness experienced. There was no history of tuberculosis, trauma nor infections.

The patient was an intelligent, light-skinned

growths Itching is usually present to an intense degree, and the general health is usually unfavorably affected, leading eventually to death In this instance, as in all these conditions which resemble the atypical neurofibromas, the microscopic examination is of greatest value

*Xanthoma Tuberosum Multiplex*—The more numerous and generalized lesions of xanthoma tuberosum multiplex involve the face, and palms, and may be soft, at times occurring as infiltrating plaques and streaks They are of a yellowish color There may be associated with this condition general debility, manifested by jaundice, cholelithiasis and metabolic disturbances, like gout and diabetes, all of which, in addition to the pathology, aid in the exclusion of neurofibromas

*Molluscum Contagiosum*—This condition which may be confused with neurofibromas is ruled out by the location of the lesions and their appearance They usually occur on the face, the side of the neck, and the genitals They are smooth, firm, semi-globular, and usually smaller more numerous and often transulcent, showing a central depression from which the milky and curd-like semi-fluid contents may be expressed

*Myomas*—These are extremely rare, but must be mentioned here since they simulate the neurofibromas in clinical appearance Their location, occurring as they do on the face, mammae, scrotum and female genitalia, differentiates them from the atypical neurofibromas Besides they are softer, somewhat pedunculated tumors, which are exquisitely sensitive to pressure and are frequently subject to paroxysms of pain

*Lipomas*—Lipomas differ in appearance from the atypical neurofibromas They are lobulated, soft tumors, at times pedunculated, in which secondary changes sometimes occur, such as ossification, oedema and liquefaction They are covered with normal skin, and are rarely found on the extremities Of course, histological examination reveals groups of fat cells, described as being held together by a capillary network forming small lobules

*Sebaceous Cysts*—Sebaceous cysts at a casual glance may look like the atypical neurofibromas, but closer observation reveals their irregular, globular shape, the feeling of elasticity which they give to the touch, their semi-solid, cheesy contents, which may emit a foul odor The microscopic examination shows a condition poorly supplied with connective tissue nuclei and blood vessels, and reveal epithelial cells undergoing fatty degeneration, cholesterol crystals and sometimes even lanugo hairs

#### CONCLUSIONS

It seems to us that the general subject of neurofibromas is of such great interest to all derma-

tologists, neurologists and physicians in general, that the atypical form to which we call attention in this paper may be of importance in further studies on the subject

This type of neurofibroma is especially interesting because it bears such a close resemblance to several other forms of cutaneous tumors, like sarcomas, sarcoids, tuberculids, gummas, and others, that although it is of fairly common occurrence, it is frequently incorrectly diagnosed clinically

The clinical and histological characteristics of these tumors indicate that they probably belong to that group of skin tumors classified by Thomas as "cutaneous neurofibromatosis"

Their existence as a form of neurofibroma must be recognized Their distinctive characteristic which we have outlined must be borne in mind in making a clinical diagnosis of skin tumors, and, it must be remembered that the resemblance to other growths may be so close that the final diagnosis often will depend almost entirely upon the microscopic findings

Regarding the fibroma simplex of Unna and the noduli cutanei of Arning and Lewandowsky, it is possible that they may be the same condition as the tumors described by us

Within recent years the tendency has been growing among neuropathologists to regard almost all fibrous tumors as of neural origin, and we venture to say that with more improved methods of examination, more precise microscopic investigations and careful interpretations of pathological findings, traces of nerve elements may be more readily demonstrated

deeper tissues of the limbs and trunk are of neural origin, the thought suggests itself that the atypical neurofibromas may possibly be the same condition described by Unna and Arning, only that with improved methods of histological study, the neurogenic basis of these tumors can now be demonstrated under the microscope.

*Von Recklinghausen's Disease*—These atypical neurofibromas, although histologically identical with the neurofibroma of Von Recklinghausen's disease, differ widely in their clinical aspect, as is readily seen from their description. Their very firm consistency, difference in location, lesser numbers, non-pedunculated appearance, firm attachment to the deeper tissues, and the fact that the contributing symptoms of Von Recklinghausen's disease, like nervous mental, structural and internal disorders, are absent, set them clinically apart from the mollusum fibrosum of Von Recklinghausen.

*Neuromas*—Neuromas which are elastic, tender, soft nodules of a purplish or pinkish color, simulating the atypical neurofibromas very closely in appearance, are distinguished from them by their paroxysmal attacks of pain, and their painful reaction to pressure or palpation. The neurofibromas are neither painful, tender, nor sensitive in any way to pressure. The pathology of neuromas also reveals the presence of ganglionic cells.

*Keloids*—Keloids are immediately differentiated from neurofibromas by their irregular outlines, and broad swelling of firm consistency, extending like ridges over the skin. They have the smooth, stretched, shiny surface of a pearly white or peculiar rosy color typical of keloids. Usually, they develop in the region of distinct traumas, as of wounds, cuts, sutures, and scars. They rarely arise spontaneously, and often recur after removal.

*Sarcomas*—The localized sarcomas may resemble neurofibromas very closely, and the diagnosis is often impossible without the aid of the microscope. The lesions, however, grow more rapidly, may show large blood vessels and pulsation, may be nodular and even mushroom-like, and are more diffuse in outline, with an occasional tendency to pedunculation. Of course, a microscopic examination will reveal the more cellular and vascular character of sarcomas, and set them definitely apart by the microscopic findings.

The Kaposi type of multiple, pigmented sarcomas shows tumors that are purplish and hemorrhagic in character, more rapid in their development and dissemination, at times involving the mucous membranes and showing plaques of infiltration and ecchymotic areas. Often ulceration complicates the condition. In our patient, in whom the lesions were disseminated and purplish in color (Case No. 4), the diagnosis depended upon the more sharply circumscribed character of the growth, the absence of flat infiltrating areas and hemorrhages, and the hard consistency

of the individual growth. Here again, examination under the microscope establishes the differential diagnosis conclusively.

*Sarcoid*—The multiple benign sarcoids (Boeck), must be differentiated from the atypical neurofibromas which they may resemble. The lesions, however, are usually flatter, more numerous, often appear on the face, may be very minute, are softer and not definitely circumscribed, show more rapid growth and dissemination, yield to arsenical medication, and leave atrophic, scar-like areas upon resolution. Although they are reddish in color, under pressure the nodules show grayish-yellow foci, suggesting the name "miliary lupoid" by which they are often designated. Histologically they show tuberculous structure.

*Tuberculosis*—A diagnosis of tuberculosis in the form of papulo-necrotic tuberculids was made in one of the earliest cases observed, because of the abundance of small, papular lesions going on to pitted scars, but close observation, bearing in mind the features of the atypical neurofibromas in respect to atrophy, differentiates them. The papulo-necrotic tuberculids may suppurate and form crusts over necrotic centers, a characteristic not observed in the neurofibromas.

*Gummas*—In differentiating gummas from the atypical neurofibromas, it must be remembered that gummas develop more rapidly, grow quickly over a period of one or two weeks to several months, and although firm at first, soon become soft and doughy, breaking down and ulcerating with a discharge. There may be several small grouped gummas, resembling the lesions described in (Case No. 2) but they show the characteristic behavior of gummas mentioned above, forming punched out ulcers with segmental or serpiginous configurations, as opposed to the firm, stationary feature of a typical neurofibromas, which never soften and ulcerate.

*Leukemia Cuts*—This condition may simulate the atypical neurofibromas. However, in leukemia, the face, head, genitals, anus and arms are more apt to become involved than the extremities. The tumors are more doughy, more numerous, and tend to develop and multiply more rapidly. Features which are absent in the atypical neurofibroma are often associated with leukemia. There are infiltrations of the skin, the presence of eczematoid and urticarial lesions and intense itching. Other factors like the adenopathy, the enlarged spleen, constitutional deterioration, abnormal blood findings and tissue examinations, of course, aid in the exclusion of neurofibromas.

*Mycosis Fungoides*—This is easily excluded from the diagnosis by its history, suggestive of inflammatory conditions like eczema, psoriasis, seborrheic eczema, urticaria, followed by the development of generalized, disseminated nodes, tumors and infiltrations which may go on to the formation of mushroom-like and ulcerated

days of Sydenham. Men of this sort found in skin diseases a subject worthy of their devotion.

And these men, from the earliest down, were not simply great dermatologists and syphilographers, they were among the greatest physicians of their time, and some of them were great citizens. This is true of Hebra, Ricord and Fournier, Erasmus Wilson and Jonathan Hutchinson. It is particularly true of the two great early pioneers, Willan and Alibert. Willan at the beginning of the nineteenth century was a personage in medicine and science in London. He was one of the great English teachers, among his students are numbered such brilliant stars as Bright and Addison, as well as his collaborator in dermatology, Bateman. Alibert, "the founder of French dermatology," held an equally great position in Paris at the same time. It is an interesting fact that the St. Louis Hospital was made a hospital for skin diseases as early as 1801 and the following year Alibert became one of its physicians. Evidence of his position in Paris at that time is indicated by the fact that one of the wards of the St. Louis Hospital and one of the streets by which it is bounded bear his name. (John Lane). Such disciples as these are sufficient evidence of the intellectual interest of the specialty.

American dermatology had its start in pupils of these European masters. Dermatology was one of the early specialties in the United States. The American Dermatological Association is the fifth in age among our national societies. As early as 1836 the first clinic in America for skin diseases, the Broom Street Infirmary for Diseases of the Skin, was established by Dr. Henry D. Bulkley and Dr. John Watson of New York. On April 2, 1867 Dr. Wm. H. Draper was appointed Clinical Lecturer on Diseases of the Skin at the College of Physicians of New York and that year gave a summer course of lectures on the subject. He was made Clinical Professor of Diseases of the Skin on March 4, 1869. In 1872 Edw. L. Keyes was made Professor of Dermatology at Bellevue Hospital Medical College and in 1875 Henry G. Piffard was made Professor of Dermatology at the University of New York City. The University of Pennsylvania in 1868 had a course on skin diseases by Dr. H. Lenox Hodge. In 1871 Dr. James C. White was appointed Professor of Dermatology at Harvard. He and Edward Wigglesworth were the pioneers in Boston. In the sixties Henry D. Bulkley, John Watson, William H. Draper and F. D. Weiss began dermatology in New York. Following them was that group who did much for American dermatology, including Freeman J. Bumstead, Morris H. Henry and somewhat younger, Keyes, Taylor, Piffard, L. D. Bulkley, Heitzman, Morrow, Bronson and George Henry Fox. In Philadelphia the pioneers were Buhring and Van Harlingen, in Chicago, Hyde, in St. Louis, Hardaway. These men were the founders of American dermatology.

And yet how modern their names sound to us. When one thinks of this small group of fifty years ago and less, it impresses upon him the rapidity of growth of our specialty.

The growth of dermatology and the constant increase in the number of dermatologists are substantial testimony to the intellectual interest of the subject, for dermatologists, unlike the surgeons and laryngologists and ophthalmologists, do not wear furs and ride in limousines. We have not the sort of specialty that leads to approbrious opulence. Men must be attracted to it chiefly by its intrinsic interest. In this respect dermatology yields to no other specialty. Its unique interest lies in the fact that practically all pathological processes can be studied in the skin under natural living conditions. This gives to dermatology unique opportunities for the study of disease processes. It has resulted in an enormous accumulation of clinical observations in diseases of the skin and in refinements in the distinction between pathological processes in the skin, which is more elaborate than exists in any other specialty. This, as a matter of fact, is used as a reflection against us, but it is no fault of ours that we have been able to accumulate a larger number of clinical facts in our specialty and have been able to make sharper clinical distinctions than can be made in other medical specialties, and that, having these facts, we have named them, for facts to be recorded must have names. Undoubtedly in time this elaboration of distinctions will be followed by condensation. But elaboration of details must come before generalizations. The detailed facts we have been accumulating are for the Darwins of the future to simplify by grand generalizations. It is nonetheless to our credit that we have furnished the stones for some of the future temples.

The potential fruitfulness of dermatology in the solution of problems of diseases in general is well illustrated in the beginnings of bacteriology. In 1837, Schwann showed that yeast found in fermenting substances was living organisms which were probably the cause of fermentation. Within two years Schonlein demonstrated that diseases might be produced by organisms, when he showed that favus was caused by an organism. Between 1839 and 1844 Gruby showed that ringworm and thrush were due to organisms and, in 1846, Eichstedt added another disease due to an organism by discovering the organism of *tinea versicolor*. Thus the century's long contention that a *contagium vivum* might be a cause of disease was settled in the affirmative by the study of skin diseases, and the science of bacteriology had its beginning.

Another illuminating illustration of the value of the study of disease phenomena in the skin in the elucidation of disease problems in general is found in our developing knowledge of sensitization. Our conceptions of allergy and anaphylaxis

## THE CAPACITY OF DERMATOLOGY\*

By WM ALLEN PUSEY, A.M., M.D., LL.D., CHICAGO, ILL.

IT is a privilege to take part in this inaugural meeting of the Section on Dermatology of the Medical Society of the State of New York. It is a section from which much may be expected, for New York state easily stands first among the states in dermatological achievement. Its pioneers in dermatology were among the earliest, it has long had, and still has, the greatest number of outstanding men in our specialty, the oldest dermatological society in the world is in this state, for many years here was published, and chiefly supported, the representative American journal in our specialty. American dermatology in fact has largely developed in the city of New York and New York state. Its dermatologists have made their impress not only upon dermatology but upon medicine as well. At least two of them, George Henry Fox and Grover W. Wende—at whose absence today we all grieve—have been presidents of this society. The formation, then, of this section can certainly not be regarded as premature.

It is desirable that men should have a high opinion of their vocations. For that reason I suspect that every one of us from time to time undertakes to appraise the worth of his life work. Certainly I have a tendency in that direction, and it seems to me that I cannot better respond to the invitation to say something on dermatology in general today than to undertake, in a small way, to evaluate the worth and capacity of our specialty.

There is hardly any better index of the worth of any field of endeavor than its vitality. And measured by this standard dermatology has every reason for self-assurance. There is a common impression that dermatology is one of the recent specialties in medicine. As a matter of fact it is one of the oldest. Doubtless one reason for this is that skin diseases are open to inspection, not only by the physician but by the patient. They are insistent in calling attention to themselves, and physicians have had their importance brought home to them as long as they have been studying disease. And so, surprising as it may be to many, we find that studies on skin diseases are among the very early manifestation of specialization in medicine, and books on the subject are among the oldest treatises on special groups of diseases. The first systematic book on skin diseases was published by Mercurialis as early as 1572.

John Lane has called attention to the fact that the first medical degree given by Yale College was to Daniel Turner of London, and Daniel Turner published a treatise on skin disease in English in 1714, and a separate one on venereal diseases thirteen years later. By the end of the

eighteenth century and the beginning of the nineteenth, men in centers of medical culture all over the world were writing on skin diseases. This early development of dermatology is convincing evidence of its importance, and the subsequent history of activity in dermatology is equally convincing evidence of its vitality. Dealing with diseases which for the most part do not involve life and death, many of which are unimportant, dermatology was nevertheless one of the first specialties to outline itself. For more than a century it has shown a vigorous and uninterrupted growth.

Modern dermatology had its beginning in Germany, France and England in the early part of the nineteenth century, among men like Plenck in Germany, Willan, Bateman and Plumbe in London, and Alibert, Bielt, Cazenave and Rayer, in Paris. Following these pioneers there was a rapid growth of dermatology that resulted in the production of a fine group of men who were developing dermatology all over Europe under such leaders as Hebra, in Vienna, Bazin and Hardy, in Paris, and Erasmus Wilson, in London.

The modern knowledge of syphilis had begun under Ricord, in Paris, in 1837, when, forced to change his own ideas by the work of Rollet, who demonstrated that they were two diseases, he used his great influence to establish the duality of syphilis and gonorrhea, and undid the mischief which John Hunter had caused fifty years before and which had retarded the development of syphilology for half a century. Worthy comrades of these, in establishing modern syphilology, were Bassereau and Clerc, in France, and Wallace, in Dublin. These pioneers founded modern dermatology and syphilology. Following them came a great generation of dermatologists and syphilologists, led by such men as Jonathan Hutchinson and Tilbury Fox, in England, Fournier and Vidal, in France, and Neumann and Kaposi, in Vienna.

This group were real men, in the very forefront of medicine in its greatest centers. Hebra, in Vienna, Fournier, in Paris, Wilson and Hutchinson, in London, are among the great names in clinical medicine of the nineteenth century. Hebra in his day stood out as the greatest teacher and perhaps the greatest physician in Vienna in a group that included such masters as Skoda, Rokitsky, Braun, Hyrtl, Sigmund, Zeissl and Pollitzer. On Fournier, in Paris, fell the mantle of Ricord at the St. Louis Hospital. Erasmus Wilson was the brilliant leader in London in the middle of the nineteenth century and Jonathan Hutchinson was one of the great clinicians, who brought down to our time the fine traditions that have characterized English medicine from the

## CLINICAL USE OF EPHEDRINE\*

By WILLIAM S THOMAS, M.D, NEW YORK, N Y

**E**PHEDRINE is an alkaloid, the active principle of a plant, *Ma Huang*, or *Ephedra vulgaris*, var *helvetica*, which grows abundantly in China. For many centuries the herb has been used in that country empirically for the relief of asthma, but it remained for workers in the Peking Union Medical College to study scientifically the effects of its active principle upon animals. Their published results show that the physiological effects of the drug closely resemble those of epinephrine, the outstanding result being stimulation of the sympathetic nervous system. The drug is now manufactured and sold in this country in the form of capsules, each containing three-quarters of a grain of the hydrochloride of ephedrine, others containing three-eighths of a grain, and still others containing similar quantities of the sulphate. One-half grain hypodermatic tablets are also obtainable, and also one ounce bottles of three per cent solutions of each of the two above-named salts of the alkaloid.

Clinical experience with ephedrine during the past two years in upward of three hundred asthmatic and hay fever patients has caused me to regard it as a remarkably efficient drug. In this class of cases I should be reluctant to exchange it for any other palliative remedy now available. I say this in spite of the fact that I continue to employ epinephrine hypodermically in sudden allergic emergencies.

The unsatisfactory results occasionally produced by it and noted by me in a former paper<sup>1</sup> are now believed to be due to imperfection in its manufacture or to improper dosage. Experience has largely obviated these drawbacks. Forms of the drug now available are better than those formerly employed and proper care in dosage has given better results. Early imperfections in manufacture permitted the presence of impurities that not only caused undesirable effects but also displaced a proportionate amount of effective alkaloid.

The hydrochloride of ephedrine appears to be the best of the forms in which the drug is dispensed, to judge from my own experience in the past. The sulphate was the first of the salts of the alkaloid to be manufactured commercially in this country and it continues to be marketed here. Formerly pseudo-ephedrine was mixed with this but I am informed that the pure sulphate of ephedrine is now available and that it is quite as effectual as the hydrochloride and that it produces no more harmful effects. The physiologic effects of ephedrine are very similar to those of epinephrine but are more prolonged. All of them are comparable to those of stimulation of the sympathetic nervous system.<sup>2</sup> The new drug and

epinephrine are strongly synergistic. So much is this so that I have been careful not to administer them together. It seems probable that experiments in their combined use may result in interesting and helpful results.

Amongst the undesirable results occasionally observed after administration of ephedrine are insomnia, sweating, cardiac palpitation, tremor, irritability of the urinary bladder, headache and nausea. Insomnia is frequently noted by patients who take ephedrine at night for the relief of asthma, but it is prevented by the administration of a mild hypnotic, such as luminal or medinal. Sweating after taking the drug is, so far as I have observed, uncommon and insignificant. As for tremor and palpitation, it is seldom necessary to give enough ephedrine to cause these symptoms. They are usually the result of overdosage and can be avoided after a few experiments in the amount of drug to be used in any patient. Irritability of the bladder caused by ephedrine has been observed in four men, each of them patients with hypertrophied prostates. One of these patients refused to continue the use of the drug after taking two doses. In the other three cases, the administration of atropin together with the ephedrine apparently succeeded in preventing further bladder symptoms. Headache was formerly often complained of by patients who were taking ephedrine sulphate and probably pseudo-ephedrine. Since employing the hydrochloride this symptom has been encountered only after the administration of overdoses.

Neither ill effects nor a tendency to habit formation have been observed in patients after long continued use of the drug. Ordinarily the dose that is effective at one time, is so at all other times. Often the dose can be diminished, but an increased amount may be required on especial occasions, as for example when a patient happens to be subjected to some influence that would bring about an attack of asthma more severe than usual. Ephedrine has no cumulative effect.

The lethal dose of the drug in laboratory animals<sup>2</sup> has been found to be fifty times as large as that required to produce its physiologic effects. No cases of serious poisoning of human beings have been met with, so far as I am aware.

One advantage of ephedrine over its older rival lies in its being effective when taken by mouth, while epinephrine must be administered hypodermically. Ephedrine and its salts contain no protein material, epinephrine does. Ephedrine solutions are stable, are not affected by light, and may be boiled without detrimental effect, it is not so with epinephrine. The relief from asthma that is afforded by an oral dose of ephedrine begins in from twenty minutes to forty minutes and lasts from four to twelve hours. Relief

\* Read before the Society for the Study of Asthma and Allied Conditions, Atlantic City, May 1, 1927.

and our increasing knowledge of the profound importance of sensitization phenomena in diseases had their beginning in the study of cutaneous reactions and have largely been developed through this same sort of study.

It is probably true that we have just scratched the surface of this potential field of medical knowledge and, necessarily, results from such study must be slow. The great fact is that these potential values exist; it can hardly be doubted that they will be utilized more and more in the solution of the problems of pathology in general. It is in this field of the application of knowledge of pathological processes in the living, as they can be observed in the skin, to the problems of diseases in general that dermatology has its most interesting prospect for the future.

One of the encouraging things about American dermatology is its flourishing state. If the law of sociology, that those who multiply most abundantly will inherit the earth applies to dermatology; dermatology, if it keeps up the pace of the last twenty years, need have no fear of it inheritance. There has been a significant increase in numbers and in distribution of dermatologists throughout the country in the last generation. Twenty-five years ago outside of New York city, the dermatologists in any of our greatest centers could be counted on the fingers of one hand. In these same centers the numbers have trebled or quadrupled in less than a generation. But more significant still is the present wide distribution of well trained specialists. Our men are getting scattered all over the country, and many of them are carrying our service to the smaller cities. This is a not only good for dermatological service to the public but it is salutary for dermatology itself. For the stimulation of knowledge for its growth and for its spread, workers must have opportunity of contacts with their colleagues in the same work. The wide distribution of dermatologists now makes this possible for us. We have our local medical organizations all over the country, so that no man is compelled, as was hitherto the case to do without that intercourse with his colleagues which is so necessary for development.

The present expansion of American dermatology and its present undoubted vigor are, I think due to the natural development of a relatively few but a sufficient number of centers of dermatological teaching. The only way to get training in dermatology or any other art is to work with a master. Formerly young men in order to get this training were compelled to go to Europe. In the last two years these young men of European training have developed their own centers in this country, centers which are fruitful of original work and active in teaching. These centers, it need hardly be said all have the inspiration of some individual leader. They are sending out year by year well-trained men who are scattering over the country as leaders in der-

matology. Some of these younger men whose training has been solely American, are now among our leaders in all of its fields; in practice in teaching and in research.

This experience it would seem has answered for dermatology the much discussed question of how specialists should be trained. The vigorous generation of younger dermatologists in America today is one of the most encouraging facts in dermatology. It leaves no doubt of the vitality of American dermatology and it gives us every reason to be optimistic about its future.

There is one tendency in medical education in general now which has dangers for dermatology as for the other specialties; and that is the apparent attitude of the controlling influences of some educational institutions that to be a specialist it is not necessary to be comprehensively trained in the specialty—not necessary to be a specialist; that the essential thing is to have a refinement of training in the fundamental sciences. The only refinement of training that he may lack is clinical refinement in the specialty he is to teach. Far be it from minimizing the importance of physiology, biochemistry, bacteriology, or pathology; they are universal necessities; but they are not the end in themselves and they do not make clinicians. The bacteriologist or the biochemist is no more by that fact a dermatologist than a physiologist is an internist, or a pathologist a surgeon. And they cannot make themselves such on independent experience. Directed training is as much necessary for making a successful dermatologist as it is for making a successful bacteriologist. The worst of it is that some men who on the basis of experience in the fundamental sciences, are trying to practice medicine do not know they need clinical knowledge and never try to acquire it. They, of course are hopeless. And we are seeing a number of them in various lines of practice. Some of them are in very important teaching positions. Dermatology, as well as the other specialties, needs to avoid this danger if it is to maintain its advance. We need the help of these men; but it is no effrontery to say that they also need our help. This is one of the dangers that dermatology, as well as the other specialties of practical medicine is now exposed to and it should not patiently accept it. Dermatology must be taught by dermatologists and dermatological experts must be developed in centers guided by expert dermatologists. There is nothing that experience has established more clearly than this.

The vigorous generation of younger dermatologists in America today is our most encouraging fact. It leaves no doubt of the vitality of American dermatology and it gives us every reason to be optimistic about the future.

The history of dermatology then and its present condition would seem to answer, in a way that ought to be satisfactory to us, the question of its capacity and its future.

## CLINICAL USE OF EPHEDRINE\*

By WILLIAM S THOMAS, M.D., NEW YORK, N Y

**E**PHEDRINE is an alkaloid, the active principle of a plant, *Ma Huang*, or *Ephedra vulgaris*, var *helvetica*, which grows abundantly in China. For many centuries the herb has been used in that country empirically for the relief of asthma, but it remained for workers in the Peking Union Medical College to study scientifically the effects of its active principle upon animals. Their published results show that the physiological effects of the drug closely resemble those of epinephrine, the outstanding result being stimulation of the sympathetic nervous system. The drug is now manufactured and sold in this country in the form of capsules, each containing three-quarters of a grain of the hydrochloride of ephedrine, others containing three-eighths of a grain, and still others containing similar quantities of the sulphate. One-half grain hypodermatic tablets are also obtainable, and also one ounce bottles of three per cent solutions of each of the two above-named salts of the alkaloid.

Clinical experience with ephedrine during the past two years in upward of three hundred asthmatic and hay fever patients has caused me to regard it as a remarkably efficient drug. In this class of cases I should be reluctant to exchange it for any other palliative remedy now available. I say this in spite of the fact that I continue to employ epinephrine hypodermically in sudden allergic emergencies.

The unsatisfactory results occasionally produced by it and noted by me in a former paper<sup>1</sup> are now believed to be due to imperfection in its manufacture or to improper dosage. Experience has largely obviated these drawbacks. Forms of the drug now available are better than those formerly employed and proper care in dosage has given better results. Early imperfections in manufacture permitted the presence of impurities that not only caused undesirable effects but also displaced a proportionate amount of effective alkaloid.

The hydrochloride of ephedrine appears to be the best of the forms in which the drug is dispensed, to judge from my own experience in the past. The sulphate was the first of the salts of the alkaloid to be manufactured commercially in this country and it continues to be marketed here. Formerly pseudo-ephedrine was mixed with this but I am informed that the pure sulphate of ephedrine is now available and that it is quite as effectual as the hydrochloride and that it produces no more harmful effects. The physiologic effects of ephedrine are very similar to those of epinephrine but are more prolonged. All of them are comparable to those of stimulation of the sympathetic nervous system.<sup>2</sup> The new drug and

epinephrine are strongly synergistic. So much is this so that I have been careful not to administer them together. It seems probable that experiments in their combined use may result in interesting and helpful results.

Amongst the undesirable results occasionally observed after administration of ephedrine are insomnia, sweating, cardiac palpitation, tremor, irritability of the urinary bladder, headache and nausea. Insomnia is frequently noted by patients who take ephedrine at night for the relief of asthma, but it is prevented by the administration of a mild hypnotic, such as luminal or medinal. Sweating after taking the drug is, so far as I have observed, uncommon and insignificant. As for tremor and palpitation, it is seldom necessary to give enough ephedrine to cause these symptoms. They are usually the result of overdosage and can be avoided after a few experiments in the amount of drug to be used in any patient. Irritability of the bladder caused by ephedrine has been observed in four men, each of them patients with hypertrophied prostates. One of these patients refused to continue the use of the drug after taking two doses. In the other three cases, the administration of atropin together with the ephedrine apparently succeeded in preventing further bladder symptoms. Headache was formerly often complained of by patients who were taking ephedrine sulphate and probably pseudo-ephedrine. Since employing the hydrochloride this symptom has been encountered only after the administration of overdoses.

Neither ill effects nor a tendency to habit formation have been observed in patients after long continued use of the drug. Ordinarily the dose that is effective at one time, is so at all other times. Often the dose can be diminished, but an increased amount may be required on especial occasions, as for example when a patient happens to be subjected to some influence that would bring about an attack of asthma more severe than usual. Ephedrine has no cumulative effect.

The lethal dose of the drug in laboratory animals<sup>2</sup> has been found to be fifty times as large as that required to produce its physiologic effects. No cases of serious poisoning of human beings have been met with, so far as I am aware.

One advantage of ephedrine over its older rival lies in its being effective when taken by mouth, while epinephrine must be administered hypodermically. Ephedrine and its salts contain no protein material, epinephrine does. Ephedrine solutions are stable, are not affected by light, and may be boiled without detrimental effect, it is not so with epinephrine. The relief from asthma that is afforded by an oral dose of ephedrine begins in from twenty minutes to forty minutes and lasts from four to twelve hours. Relief

\* Read before the Society for the Study of Asthma and Allied Conditions, Atlantic City, May 1, 1927.

obtained from a hypodermic dose of epinephrine usually lasts from one hour to three hours. Ephedrine may be given hypodermically.

The proper oral dosage of ephedrine varies considerably in different persons of the same weight. The reason for this is unknown. Failure to obtain satisfactory results with the drug is occasionally due to adherence to some arbitrary rule of dosage. A more rational practice is to experiment with its effects upon each patient, if need be, until the best result is achieved. The proper amount required by any given patient may be conveniently ascertained by beginning with the administration of an aqueous solution of the drug. In a three per cent solution, one minim contains two milligrams of the drug. The average dose for an adult is forty milligrams of the drug, or the amount contained in twenty minims of the three per cent solution. Should this dose fail to relieve the patient of his asthmatic or other symptoms the next dose should be increased. If this amount, on the other hand, relieves but in addition causes tremor or palpitation, the amount next given should be diminished. When the proper dosage for an individual has been determined, the drug may be given in capsules or in tablets if preferred. Infants and children take ephedrine well. I have never observed ill effects in them nor failure to relieve asthma.

Adult patients who are liable to suffer from asthmatic attacks will find it convenient to carry about with them phials of one-half grain tablets of ephedrine. One, two or three of these may be swallowed when needed. In order that the beneficial effect of ephedrine may be prolonged, the drug can be administered in a rectal suppository with cocoa butter. The dose is then twice that given by mouth.

Ephedrine as a palliative remedy for asthmatic attacks finds occasion for use under such circumstances as the following:

- 1 In persons seen by the physician for the first time during an attack
- 2 In persons who are awaiting the completion of a series of protein or vaccine tests for hypersensitiveness and in whom attacks are occurring
- 3 When specific or other treatment has been tried and has failed to relieve

Patients who are about to undergo sensitization tests should be cautioned not to seek relief in ephedrine within a period of twelve hours before such tests are to be made. This drug, like epinephrine, temporarily prevents the appearance of positive reactions to specific tests for sensitiveness. Temporary relief may be sought, under these conditions, in the use of morphine or inhalation of the fumes of burning stramonium leaves and potassium nitrate powders or in the rectal administration of oil-ether. Such makeshift palliative remedies are not, of course, chosen ordinarily, but at least they have the advantage of appearing not

to interfere with bodily reactions to specific diagnostic tests.

Ephedrine is, perhaps, at its best when used as a preventative of asthmatic attacks. Patients who suffer regularly from daily or nightly paroxysms will often remain asthma free for long periods of time and suffer no harm if they receive properly administered doses of the drug taken once, twice or three times in each twenty-four hours.

Another useful field for employment of the drug may be found in its power to prevent constitutional reactions resulting from prophylactic treatment injections of proteins, whether they be of air borne substances (pollen or epidermal) or of foods.

An important property of ephedrine is its ability to shrink swollen nasal mucous membranes.<sup>3,4</sup> After the application by swab or spray of a three per cent aqueous solution to the nasal passages of a patient suffering from coryza or hay fever, relief follows in from one to five minutes and lasts one or two hours and sometimes longer. The local effect ceases gradually and is not followed by after-congestion as is unfortunately the case subsequent to the local application of epinephrine solutions.

When ephedrine is used as a spray, it is preferable to use an all-glass or hard rubber atomizer, as the solutions of ephedrine salts have been noticed to become turbid and lose their beneficial effect if allowed to stand in contact with metal.

Even though a nostril be completely occluded by swelling, it will become patulous after an application or two of ephedrine solution. The nasal mucosa of hay fever patients has been observed to shrink and relief of symptoms to follow administration of ephedrine by mouth. This fact is of great interest to the physician who treats hay fever. In those hay fever subjects to whom I have given the drug by mouth, I have at the same time used it locally in their nares and by this combined use, its beneficial effects have been satisfactory in all but one case. Patients who use the watery solution in a hand spray are usually advised to follow this by snuffing up into the nostrils a pea-sized portion of white vaseline containing three per cent of ephedrine and one-half of one per cent menthol.

Ephedrine will, perhaps, find future use in fields as yet untried. If administered to patients together with therapeutic injections of immune sera and antitoxins, it would probably prevent possible anaphylactic shock. Serum sickness would probably be relieved by it as much as it is by epinephrine, and for a longer period of time. Certainly ephedrine<sup>5</sup> has given temporary relief from discomfort in the few cases of urticaria in which I have used it.

Dr W. A. Bastedo recently inquired if ephedrine might not be useful, if given by mouth, in checking gastric hemorrhage by reason of its local vaso-constrictor effect. It is evident that

inasmuch as this drug (unlike epinephrine) causes constitutional effects after absorption by the mucous membrane of the alimentary tract, it could not be used for such a purpose. An amount of it sufficient to shrink the gastric mucosa or constrict bleeding vessels would seemingly produce also severe general physiologic effects.

Ephedrine appears to have before it a future of usefulness in the surgical world by reason of its power to blanch and shrink mucous membranes for a longer period of time than does epinephrine. Not only will it come to be widely used locally in rhinologic surgery, but probably also as an auxiliary to local anesthetics in surgery of the urethra and urinary bladder.

Contraindications to the use of ephedrine are not often met with. They cannot be foretold at present, but are revealed only by trying it. Most

of the untoward effects produced by it can be overcome, either by lessening the dosage or by antidotes such as atropine or luminal. The drug is apparently entitled to a place in the category occupied by such drugs as morphine, digitalis, atropine and the few other drugs that can be depended upon to produce effects in the human organism that make them important remedies in the relief of suffering.

### SEX COMPONENTS IN MEN AND WOMEN

By ROBERT KINGMAN, M.D., F.A.C.P., BROOKLYN, N. Y.

IT IS a matter of common observation that males and females so-called, resemble each other much more closely in all external characteristics, with the single exception of the formation of the reproductive organs, at the two extremes of life than during the intervening years. Infants, regardless of whether they are later in life to function as male or female, are apt to look very much alike, and elderly people, particularly if beyond the allotted span of three score and ten, lose many of the secondary sexual features that sharply differentiated them during their prime. The facial appearances of an elderly woman and an elderly man are singularly alike. The male voice may become thin and piping, and that of the female deeper and fuller. The natural fat pads and rounded curves of the woman are lost by absorption, and her body takes on the more muscular and angular outlines of the man. The beard of the man softens and thins out, while the woman is apt to develop a superfluity of hirsute adornment.

This close outward resemblance of the sexes in infancy and senility arouses no surprise, we are accustomed to look upon these periods as more or less devoid of sharp sex differentiation. But when seen in early and middle adult life, the period of most intense reproductive activity, women who look like men and men who look like women draw our attention as being in a rather uncomfortable way decidedly different from the normal. Why this should be can only be understood by a consideration of masculinity and femininity on some other basis than that of the reproductive functions alone.

Our sex is ordinarily assigned to us simply on the ground of the reproductive faculties. At the present time a man is a man and a woman

a woman from the point of view of these functions alone a most unsatisfactory confusing of a part with the whole. Study of the combined sex characteristics—mental, emotional and physical—have brought biologists to the conclusion that human beings cannot be described bluntly as male or female and assigned categorically to one sex or the other. "Male and female created He them," should refer to each individual, not to a pair. The hundred per cent masculine man exists as a hypothetical ideal only, and just so the hundred per cent feminine woman. Our world is populated by beings composed of both masculinity and femininity in all imaginable variety of percentages, between the fifty-fifty half and half bisexual and the ninety-nine and forty-four one hundredths approximation to unisexual completeness.

It cannot be lightly assumed that every "John" and every "Jane" are representative of their apparent sexes because they have been dubbed "male" and "female." It is a scientific fact that total maleness and total femaleness are merely abstract conceptions of which concrete examples do not occur biologically. And yet such sayings as "waiting for Mr. Right," "So-and-so are quite unsuited to each other," "Every Jack has his Jill" have arisen from an obscure presentiment based on an accurate physiological law, that every man and every woman possesses certain individual characteristics which qualify or disqualify him or her for marriage with any particular member of the opposite sex, and that this man or that woman cannot be substituted for another without creating disharmony.

If one compares the pen portraits of a number of women with whom some famous man has been in love, it is apparent that they all

closely resemble each other in features, coloring and contours. It is precisely the same with all of us, every girl who strongly attracts a man recalls to him other girls that he has loved before. It is commonly recognized that certain individuals of the opposite sex are distasteful to us, that others leave us cold, while others again may stimulate us until, at last, some one appears who seems so desirable that everything in the world is worthless and empty if we cannot possess this onliest one. Is there a general law by means of which the specifications of that ideal person may be summed up for each one of us? If, as seems probable, every male type has its female counterpart with regard to sex affinity, it ought to be possible to formulate a definite law expressing this relationship.

Such a law, founded on known biological and psychological principles, has been formulated. In substance it parallels the dictum "Likes repel, unlikes attract," and may be stated as follows—For satisfactory sex affinity it is necessary that a complete male being and a complete female being come together, even though the proportions of femininity and masculinity be unevenly distributed between the two individuals. If every man were a complete male and every woman a complete female, all that would be necessary to comply with this law would be for any man to be joined to any woman. But, as has been intimated previously, the complete male and the complete female do not exist as separate entities. Every individual is a combination of a certain amount of maleness and another certain amount of femaleness.

Hence, to comply with the rule, everyone must find his exact complement, that is, another individual who will contribute just that amount of the two sexes necessary to endow their joint partnership with 100% of maleness and 100% of femaleness. For instance, in a man so-called, but possessed in fact of 51% of masculinity, the remaining 49% of make-up must be feminine, and for satisfactory union he must mate with a woman, so-called, who will contribute 51% of femininity and 49% of masculinity to the union. The sum total of the qualities of these two individuals will then amount to 100% of male and 100% of female. Again, a man 75% masculine and 25% feminine will obey the law if he picks out a woman 75% feminine and 25% masculine. The sum total again equals 100% of male and 100% of female. Similarly the biological complement of a woman possessing 63% of femininity will be a male possessing 37% of femininity, while a woman of only 14% maleness will enable a man of 86% maleness to satisfy the equation.

Love at first sight is nothing more than an accidental fulfillment of these requirements: the man and woman happen to possess the

exact proportion of masculinity and femininity to balance and complement each other. On the other hand marital incompatibility is, nine times out of ten, the result of a union between a man and a woman whose percentages of masculinity and femininity do not even approximate each other's requirements. If, under such conditions, the natural complement of either appears on the horizon in the form of a man or woman presenting the proper sex combination of maleness and femaleness, nature steps in to readjust the difference of potential as inevitably as in the sphere of electrical discharges, and the inclination of the unhappily mated one to desert his or her makeshift at once asserts itself. This is none other than the fundamental idea of Goethe's "Elective Affinities," that fascinating romance which deals with the problem in terms of a future psychology at that time as little realized as was the fact that the author himself was in later life to suffer the full force of a similar disrupting experience.

If the law of sex complements is true as a general proposition, a knowledge of the method of its application to individual cases should be of vital importance to every man and woman. Unfortunately the use of eugenics in the mating of the human animal is not yet countenanced by convention. Thoroughbreds and pedigreed stock are its results in other animals. The human race must still breed on in the age-old hit or miss fashion of our forefathers.

Nevertheless, some simple tests for which no scientific knowledge other than a shrewd judgment of character and physiognomy was necessary may be suggestive. Photographs of a number of prepossessing women were selected, each of whom was judged to be a good example of some definite proportion of femininity, and a carefully selected group of men were invited to select the photograph which appealed to them as the most beautiful. It was possible in each case to predict the choice by estimating the make-up of the man in accordance with the rule we have cited. He invariably chose as the most beautiful woman the one whose sex proportion was most nearly the complement of his own. Another group of men were asked to present the investigator with a number of photographs among which was one which particularly appealed to them. Again, an application of the rule made it possible to point out the individual preference. By the same method it has been possible to describe to men and women, without any aid from them, their ideal of the opposite sex, and often in more minute detail than they themselves could have done. On the other hand, the qualities that repel them in the opposite sex have been pointed out and brought to their realization often for the first time, although for the most part men appreciate more readily the

characteristics that repel them than those that attract

For accurate results it must be appreciated that sex beauty and esthetic beauty are two entirely different matters. Many a man considers a woman beautiful who, from the aesthetic standpoint is not merely indifferent in looks but actually ugly. Aesthetics have to do with beauty in the abstract or absolute, a conception from which all sex influence must have been entirely eliminated. It frequently happens that a man is captivated by a particular woman and raves about her beauty, while his friends cannot imagine what he sees in her to admire. It is his sex that is doing the raving, for nature is trying to force him to choose in a mate what he lacks in himself. His friends with their differently balanced sex components in the matter of male and female elements, naturally cannot see with his eyes. A man, very nearly evenly divided as to sex, was heard to exclaim, "there's a fine woman," when he saw an actress of similar makeup to his own who had a slight tendency to a beard, a deep sonorous voice, and very little hair on her head. His 49% of femaleness needed her 49% of masculinity to supply his own deficiency, and what to a sufficiently masculine man would have been repugnant virago was to him lovely woman. For every man the word "woman" has a different meaning, and for every man it stands for the same thing. Whatever and however she may be, if she satisfies what he lacks, she is all woman to him.

This natural law of selective affinity between the sexes, not dissimilar to other natural laws has been deduced from innumerable experiments and exhaustive research in plant and animal life. It shows that sex exists in men and women blended in the most diverse proportion of maleness and femaleness. Nature is always trying to bring together pairs of human beings the component individuals of which are perfectly adapted to each other. Our spontaneous selections and rejections are unconsciously made in accordance with this law. The force with which two individuals whose sex is compounded in the proper proportions

for harmonious union tend to rush into each other's arms, is not less than that of the repulsive action which develops between the mismates of social conventions. The process is literally and figuratively analogous to that which causes solution and dissolution in the chemical laboratory.

From all of which may be derived sufficient explanation for the fact that the more femaleness a woman possesses, the less will she understand a man and the more will his sex character influence her, and that, the more manly a man is, the less will he understand women and the more readily will he be influenced by them. Those men who claim with justification to understand women perfectly, are themselves very nearly women in fact. And womanish men know much better how to treat women as they wish at heart to be treated than do manly men. The latter, except in rare instances, learn how to deal with women only after long and disappointing experience, and even then most imperfectly.

The present-day apeing of masculinity by woman is not the passing fad that it has so often been at recurring intervals in the past. The so-called woman question has never been settled for long for the good and sufficient reason that woman herself has never been a settled quantity. It is demonstrable at the present time that the ratio of her inherent masculine and feminine components is steadily changing. This change is in the direction of an increase in the mannish with a corresponding decrease in the womanish attributes quite apart from any adoption of the outward apertenances and political prerogatives of man.

If the future is as unlike the present as the present is unlike the past, it would appear that the two sexes may so approach each other as to be practically interchangeable in all respects but one. And the experiments of Jacques Loeb and his successors with artificial methods of fertilization in lower forms of animal life have indicated that even this one may not be as indispensable as most of us would like to believe.

## DIFFICULT SURGICAL PROBLEMS IN UROLOGICAL PRACTICE\*

By DAVID M DAVIS, MD, ROCHESTER, N Y

THE surgical principles according to which difficult cases are treated are well known to all of you, but it may be of interest to review briefly some of them as they appear in urological practice

If one analyzes roughly the elements which make a case difficult, one can perhaps make three groups, which overlap each other in many individual cases. First Cases in which the serious and extensive nature of the diseased condition for which surgical treatment is intended cause the treatment to be difficult and hazardous. Second Cases in which there is marked impairment of the patient's general condition as a result of changes secondary to the condition at which surgery is to be particularly directed. This group is especially prevalent in urological practice, the secondary damage being that due to urinary obstruction, often with the addition of infection and stone formation. Third Cases in which the patient's general condition is greatly impaired by other conditions unrelated to that at which surgery is to be directed. Among such conditions which are most common may be mentioned senility, myocarditis or other cardiac disease, hypertension, diabetes, organic nervous diseases, anemia, chronic bronchitis, pulmonary tuberculosis, etc. It is, of course, evident that certain cases fall in two or often all three of these groups, when, of course, the difficulties are magnified.

In the process of "getting the patient into condition to operate," numerous considerations apply. First Unless by some simple means the patient's condition can be made to improve rather than to become worse, waiting increases the difficulties instead of lessening them. Secondly If the patient's condition is in any way precarious, it is better to employ fractional procedures, doing as little as possible each time. Thirdly In selecting the order of the fractional procedures, one has to be guided by thinking which will be the less hazardous for the patient, and which will be most likely to cause the greatest subsequent improvement before other procedures are undertaken.

Generally speaking, in urological practice the first step to be undertaken is to relieve conditions secondary to the principal lesion, particularly obstruction, infection and hemorrhage. Urinary obstruction, of course, is very prevalent in urological conditions and may occur at any point in the urinary tract. Obstruction below the bladder is relieved by catheter or suprapubic drainage, above the

bladder by ureteral catheter, by nephrostomy or sometimes ureterostomy. Relief of the obstruction is of the greatest aid in combatting infection. In my opinion it is much better to regard these problems along the lines I have indicated rather than to think of applying, in a dogmatic way, certain procedures which are spoken of, for example, as two-stage prostatectomy or two-stage nephrectomy. The preliminary or restorative treatment cannot be given over any predetermined length of time but must be continued until the desired results are obtained.

During this same period, proper treatment is directed to any unrelated condition which may be present. Digitalis in cardiac conditions and insulin in diabetes are of the greatest aid.

In illustrating the above remarks, I might first mention one case in which the difficulties proved too great to overcome and another in which the result was not good because not quite sufficient attention was paid to sparing the weakened patient. The first case is that of a man 55 years of age, who had noticed blood in the urine for a period of eighteen months. The amount of blood had increased and with this had come increasing frequency, difficulty and pain. Treatment was not sought, however, until the bleeding had become very great. At the time this patient was first seen, clots of blood were being expressed continually from the urethra, with much pain, and there was marked pallor and weakness. Cystoscopy was impossible under these conditions but the bladder was not to be discovered above the symphysis and a catheter found no urine or collection of fluid therein. A short period of observation showed that the blood was un-mixed with urine and it was, therefore, felt that relief of some kind, presumably from obstruction of the ureters by malignant growth in the bladder, was urgent. Exploratory operation disclosed the bladder very small, stony hard and with thick walls. No effort was made to open it but at a secondary operation, 24 hours later, one ureter was brought out and sutured to the skin edge. This ureter was dilated to a diameter of 2 Cm and contained clear urine under high tension. Complete urinary obstruction had existed for so long, however, that the patient did not rally and died in spite of the relief of the obstruction. Here hemorrhage and urinary obstruction had combined to injure the patient so much that recovery was impossible. The second case was that of a man 86 years old, suffering from severe urinary obstruction of long standing due to prostatic hypertrophy. There was in addition a small diverticulum of the bladder,

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls N Y May 10, 1927

about 3 cm in diameter. Suprapubic cystostomy was performed and at this time the patient's general condition seemed so good that I yielded to the temptation to remove the diverticulum. This procedure was unusually easy, the entire operation consuming but 25 minutes. Following it, however, the patient's blood pressure fell in spite of all efforts to restore it, intra-arterial thrombosis occurred and death resulted in two and a half days. Here the very advanced age of the patient made a procedure, which would have been very easily borne by a younger man, highly dangerous.

The third case, somewhat similar to the last one, shows how much better results may be obtained by following out rigorously the rules of treatment prescribed above. A man, aged 70, had suffered for ten years from urinary obstruction due to a greatly enlarged prostate, but had not applied for treatment. He finally had a seizure during which he became unconscious and remained so for ten days. He recovered partially from this and at this time an enlarged prostate and a very greatly distended bladder were discovered. His general condition was poor in the extreme. He was very weak, systolic blood pressure of 180 mm., and extreme mental depression were present. Catheters failed to enter the bladder so that suprapubic drainage was instituted at once. Incision was made in the midline and a tube inserted. The patient immediately began to improve in every way and after a time examination of the bladder by means of a cystoscope inserted through the fistula and also a cystogram, showed that an enormous diverticulum was present which had pushed the bladder far over into the right side of the pelvis. The tube had been placed in the diverticulum. There were three stones in the bladder and two in the diverticulum, and an enormously enlarged prostate was projecting up into the bladder. Drainage was continued for a period of five weeks and transfusion of blood also given. As a result of this, the patient's condition improved so much that he was eventually able to withstand removal of the diverticulum, the stones and the prostate at one operation and was completely relieved of his urinary troubles.

Case 4 is that of a man 43 years of age, who had suffered for about three years from urinary obstruction. Complete retention finally ensued. Examination at that time showed a large diverticulum of the bladder. Operation was performed by another surgeon, after a short period of preparation by interval catheterization. The diverticulum was removed successfully but the wound healed slowly and a small urinary fistula persisted. At this time I saw the patient and felt that a contracture of the vesical orifice was present, the prostate not being enlarged. Two large pieces were

removed by means of the prostatic punch but in spite of a repetition of this procedure a month or two later, the fistula still persisted and remained open for a period of thirteen months. At this time a plastic operation was performed for the removal of the fistula and primary closure of the abdominal wall. This resulted in healing but shortly afterward the patient began to have severe pain in the right side of the back and the fistula reopened. The urine contained large quantities of pus and blood and was heavily infected. X-rays and pyelograms showed the presence of two large rounded stones in the right kidney and a large stag-horn or coral calculus in the left kidney. The right ureter was obstructed in the region from which the diverticulum had been removed and catheters could not be inserted. Phthalein test was very poor,  $1\frac{1}{2}\%$  in the first 15 minutes, 18% in the second 15 minutes 20% in the second half hour. The patient was weak, emaciated and discouraged. Although nephrolithiasis, with infection, was present, it was in his favor that the urinary obstruction had been relieved and the NPN was only 45. It was decided, therefore, that operation was feasible and the two stones in the right kidney were removed through a pyelotomy incision. This allowed drainage of the kidney and the patient improved remarkably. Sometime later I succeeded in passing bougies up the right ureter and the kidney fistula then closed. The patient put on 15 pounds of weight, the bladder fistula remained closed, and he seemed well on the road to recovery when pain commenced in the left kidney and it became necessary to remove the stag-horn calculus. His improved condition, however, allowed this to be carried out without any great difficulty and at the present time he considers himself well, has returned to work and the urine is almost clear. The entire period of treatment in this patient covered nearly 20 months, but each thing that was done improved the patient's general condition and helped prepare for the next step.

Case 5 is that of a woman aged 55, who had suffered with pains in the right side and right back for 15 years, with occasional attacks of marked urinary urgency. There were also occasional chills and fever, shortness of breath, swelling of the ankles, and headaches. She had had a thyroidectomy 8 years before. When first seen there was very marked tenderness in the right kidney region, with rigidity of the muscles. Blood pressure was 160/80. The urine contained large quantities of pus and streptococci. Phthalein. First hour 25%, Second hour 20%.

Cystoscopy was performed, showing purulent urine coming from the right ureter. A right pyelogram was made, the outline of which was very abnormal, the kidney being rotated an-

teriorly From the nature of the abnormality, the probable diagnosis of polycystic kidney, with pyonephrosis, was made Symptoms, however, grew worse and there were chills and high fever A catheter was left in the ureter but since this failed to drain, operation was performed the following day at which time the pelvis of the right kidney was drained by an incision through the parenchyma The diagnosis of polycystic kidney was confirmed, the cysts, however, being small and much functional tissue remaining The next day the patient's NPN was 66 but gradually improvement occurred and continued for a week At this time pain commenced in the left side Fifteen days after the first operation it was evident that the infection had spread to the left kidney The pyelogram of the left side is also extremely abnormal but quite different from the right side There was no doubt, however, that it also represented a polycystic kidney Left nephrostomy was, therefore, performed, the pelvis again being found full of pus Again there was improvement but this was interrupted by a phlebitis of the left femoral vein and secondly by a recurrence of pain in the left side, with a tender mass in the left flank below the kidney Efforts were made to open this through the incision, with a long clamp, but they were unsuccessful and 15 days after the second operation, a third operation was performed, under local anesthesia, at which time the peritoneum was pushed back and a retroperitoneal abscess was found around the ureter and below the left kidney Following this drainage, the patient was extremely ill for two weeks, but at

this time real improvement commenced and the chills and fever, which had occurred from one to three times almost every day for a period of over three months, finally ceased The infection had undoubtedly damaged the kidneys further since the phthalein appearance time was now one hour, but, in spite of this, the wounds healed well and normal voiding occurred from the bladder After a convalescence of nearly ten weeks, the patient was discharged, able to walk with crutches She has now gained 20 pounds and, except for some arthritis, of the knees and hands, some swelling of the ankles and some burning on urination, feels quite well This patient has not been restored to complete health, but, in view of the fact that she had bilateral pyonephrosis and polycystic kidneys, with perinephric involvement on the left, it is remarkable that she should have recovered at all That she did so can be attributed to prompt drainage of all foci of pus as soon as they were discovered by procedures which were as rapid and gentle as possible and to persistent supportive treatment, which included infusions and transfusions, between these operations

My conclusion is to emphasize the dictum, which has been put forward so often, and ignored so often, to "treat the patient first, the disease afterward" The true surgeon will eliminate "rule of thumb" from his work and, using the practiced eye of a keen clinical observer, will do only that which he knows needs to be done and which he believes the patient can endure

## THE PREVENTION AND TREATMENT OF ACNE VULGARIS\*

By HERBERT H. BAUCKUS, M.D., BUFFALO, N. Y.

**T**HIS paper represents a plea for the early recognition of certain disorders in the skin of the young individual so that proper treatment may prevent the development of the more severe and disfiguring lesions of acne No effort will be made to review the entire treatment of acne and for purposes of brevity the distribution on the face alone will be considered

Of first importance is the fact that all physicians in every kind of practice ought to realize the necessity of advising treatment of the first early seborrhoea and comedones which nearly always mark the beginning of acne The parents of the child with blackheads usually do not consult the dermatologist for an opinion on this disorder before the acne

is quite generally developed Too often the advice of both layman and physician alike, to the early case of acne is that—"in time it will get well," or, "you will outgrow it" Perhaps more stress ought to be laid upon the fact that acne becomes very many times a serious handicap and, contrary to popular opinion, extends throughout the life of the individual in some instances Early in the school age the victim suffers from embarrassment and this mental distress is likely to be increased as the individual approaches the age of maturity Much of lack of confidence and of poise occurs when the acne patient begins to allow this disorder to deter him or her from a proper interest in society

We are all familiar with the complaint of the young man in business that his acne lesions and scars are daily and keenly noticed

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927

by customer and business associates. Certainly any measures we can take to prevent the more serious lesions of acne and bring about timely eradication of this disease will be beneficial in increasing the happiness of the human race. To this end it behooves us as dermatologists to urge parents and physicians alike to appreciate the importance of the early recognition and treatment of acne.

Realizing full well that all the etiological pathology is not entirely clear-cut, it yet seems that the explanation of Whitfield reasonably answers for the greater majority of patients. (1) Whitfield regards the excessive oiliness and seborrhoea as a primary cause of the disorder. The microbe bacillus of Unna and Sabouraud grows freely in a favorable media formed by the oil and lodges in the neck of the patulous follicle of the oil gland. Here, mechanically or as a toxin, the acne bacillus irritates the epithelium which now encysts the organism with horny cells. Following this, suppurative results by infection with the ordinary staphylococcus, resulting in many instances in the formation of scars. It follows then that the early appearance of excessive oiliness of the face merits attention to treatment.

Although the time of puberty is often spoken of as the beginning of the acne stage, it is a fact that the seborrhoea usually is in existence before this time, being already quite prevalent in children of nine to ten years of age. Ayers has reported a few cases of acne appearing in the infant. (2) From the time the child begins school, then, inspection should be made for beginning signs of acne. I wish to here call attention to the advisability of treating seborrhoea of the face by a routine washing with soap and water during school hours. The school child sits at his desk for several hours of the day. He passes his hands over his face repeatedly. Dust and dirt and other foreign materials and quite often perspiration are wiped into, and occlude, the sebaceous orifices. In like manner are pus organisms apt to be inoculated. If school children, especially those in the grades, were given a short period to wash the face and hands with warm water and soap there would be much less comedo formation, we would see fewer of the severe cases of acne, and of course there would also be a reduction of various other infectious diseases of the skin. If this procedure is not possible at school, the face and hands ought to be washed at home immediately following dismissal from school. Most school children do not wash until time for the evening meal. Of course, in certain diseases of the skin it would be unwise to indulge in frequent washing of the face, but by far the greater number of chil-

dren have an active sebaceous secretion of this part. Especially at the time of puberty, when the comedone formation is apt to become more active, would it be desirable to wash the face five or six times a day. Touching the face with the hands as often as we do, it is only logical to expect we ought to wash the face as many times a day as we do the hands. Lack of real sebaceous cleanliness of the face is often a means of bringing on acne in the young.

This cleansing process will reasonably take care of a large number of potential acne cases. In those who go on to the stage of comedo with epithelial proliferation of so horny a nature that the removal of a sebaceous plug is quite difficult, the use of a local application becomes necessary. The ordinary lotio alba in these early cases is quite productive of good results. Care should be taken to have the lotion properly prepared and sometimes it is well to note on the prescription that the ingredients be dissolved separately before mixing them. A dram of each of potassium sulphuret and zinc sulphate to four ounces of distilled water is the ordinary strength to be used. The addition of one per cent alcohol to this mixture will make it keep better and tend to retard the formation of offensive odors. The patient is instructed to apply enough of the lotion, preferably on retiring, so that a film of powder is visibly remaining on the skin. I find that rather than apply stronger preparations in obstinate cases, it is better to make more frequent applications of this simple lotion and avoid the risk of irritating the skin. Quite too often we forget that an irritation of the skin is an important step in breaking the barrier against infection of the cutaneous surface. Along with this treatment it is well to bar the use of all oily cosmetics. Sometimes, when the skin shows signs of temporary harshness, the application of cold cream is permissible and of benefit, always, however, with the proviso that a soap and water cleansing will follow within a reasonable period. Finely powdered talcum assists in soothing the skin and also is absorbent to the sebaceous material. However, each application of powder or other cosmetic should be followed by a soap and water cleansing of the skin before another application is made. Otherwise there is the hazard of having portions of these materials inspissated into the sebaceous ducts.

In emphasizing this local treatment there is no desire on the part of the writer to minimize the important part played by other general measures in the treatment of early acne. Proper diet, with a regular and sufficient time for eating, care of constipation, outdoor life, proper rest and sleep, care of gastro-intestinal

disturbances, attention to the causes of secondary anemia, the heeding of pelvic disorders in the female, and the possibility of tuberculosis, are well known to merit careful thought in the treatment of acne. In some patients the endocrines will be entitled to consideration. Certain occupations in which grease, dust and dirt, and other foreign materials, especially irritating oils, accumulate on the face, are favorable to the development of acne. Wearing the hair tightly fitted against the skin often causes severe types of acne of the forehead in young females. Many cases of chronic recurring acne are in some measure caused by an accompanying seborrhoea of the scalp. The scalp of the individual with acne ought always to be examined and treated when necessary. Sometimes it is forgotten that a mercurial preparation should not be used on the scalp at the same time that a sulphur lotion is used on the face, as the formation of fine black precipitates may ignominiously occur on the face as a result of the chemical action of the two elements.

A point often overlooked is that the ingestion of bromides or iodides in a person having comedones is often the means of converting a case of simple blackheads into one of acute pustular acne which may become quite intractable and chronic, and lead to irreparable scar formation. Of course physicians know that bromides and iodides produce papules and pustules in some patients, but their attention ought to be called to the fact that every effort should be made to avoid prescribing these drugs to individuals presenting evidences of excessive seborrhoea with comedones.

Advice to the young patient afflicted with acne should be to the effect that the process is one due largely to an over-secretion and faulty elimination of the oil gland system and that this action is likely to persist over a considerable period of time. If this advice is given at the onset of treatment, much misunderstanding is avoided and the patient learns to take care of the skin with frequent washing and in such a manner as to minimize the amount of comedo formation. So many patients have the fallacious idea that a certain number of office treatments over a definite period of time will bring about a cure of their acne. It is only in the nature of things that the sufferer from acne has an excessive seborrhoea which is apt to continue for an indefinite period. Cognizance is here taken of the fact that a small percentage of patients with acne do not have a noticeable over-secretion of the sebaceous glands.

There will, of course, be certain of our early treated cases that for some reason or other will develop a more severe acne. These, with the cases of outspoken pustular acne of

mild degree coming under treatment for the first time, constitute acne simplex as a dermatologist usually sees it. Without attempting to outline the entire treatment of this stubborn disorder which will be much benefited by the local and general measures before alluded to, reference will be made to a few points in treatment which the writer has found deserving of consideration. I have found no benefit from the use of a vaccine made from the acne bacillus. The use of staphylococcus vaccines, autogenous or stock, usually ends in disappointment, but occasionally is productive of benefit in combating pustule formation. It is idle to expect any result from the vaccine against seborrhoea, comedo and follicular hyperkeratinization, and yet we often find cases of blackheads and mild acne treated with vaccines to the exclusion of all other forms of treatment. I use the vaccine only in cases of severe pustule and furuncle formation. Except in selective and severe cases, I believe the mechanical removal of small blackheads and the evacuation of small pustules does as much harm as good, since these lesions will continue to reform until there is a general change of the skin. In the trauma of mechanical removal, deeper infection and scarring may ensue. Of course, there are cases in which special lesions require attention along this line.

Careful treatment of the early stages of comedo and simple acne will eliminate the necessity of using X-ray in many instances. No one seriously questions the wonderful efficacy of the X-ray in the treatment of acne, but the increasing enthusiasm of the past few years has carried us to the place where we are made to keenly realize that a certain definite amount of harm has resulted from indiscriminate and injudicious employment of this agent. X-ray takes the position of the adjuvant and not the specific in the proper treatment of acne.

A few X-ray applications to the early case of stubborn comedo will often check the seborrhoea so sufficiently that other continued measures will suffice. In outspoken acne, of course, the aid of the X-ray is to be sought. A series of from ten to twelve treatments in correct dosage and at proper intervals constitutes a judicious therapy. I do not believe that X-ray should be used in dose strong enough to preclude the use of lotio alba at the same time. In these days of perfected technique, we seldom see the result of a single over-dose of X-ray, but we are becoming increasingly familiar with the distressing sequelae of too long continued treatment. The patient, having received so much benefit from the first treatments with X-ray, urges its continued use. But to pursue more or less iso-

lated lesions of acne over various areas of the face in an effort to exterminate all of them is to invite a disaster for which the owner of a permanently wrinkled, atrophic, and telangiectatic skin will not thank the physician

Everyone treating acne ought, of course, to be familiar with the presentation of the subject so thoroughly covered by MacKee.<sup>3</sup> I believe that the treatment of acne with X-ray should be attempted only by the dermatologist. In my work, I use the X-ray mostly to control the excessive oiliness and the keratinization at the sebaceous orifices but not depending on it very much for taking care of pustules. In dealing with pustules, I find that ultra-violet ray is of great use. Where sebaceous activity has been lessened by X-ray and other treatment, recurrences under quartz lamp therapy are not so common as generally supposed. It should be understood that ultra-violet ray does not atrophy the sebaceous glands and that its action is mainly against the staphylococcus. Its desquamating action also is of value. In his experience in treating acne with ultra-violet ray and X-ray the writer has had no bad results from combining both methods of treatment.

#### SUMMARY

1 Children displaying unusual activity of the sebaceous glands should be considered as potential cases of acne

2 Washing the face and hands of the young freely with soap and hot water is a good hygienic measure and will prevent a great

deal of acne. It might be feasible to indulge in this practice in the school

3 Children with blackheads ought to be treated for this condition

4 Physicians should avoid prescribing bromides and iodides to individuals having blackheads unless such drugs are absolutely necessary

5 Vaccines in the treatment of acne are of use only against the staphylococcus

6 X-ray is not necessary in every instance nor is it to be used as the only means of treatment. It is of value mainly in dealing with sebaceous over-activity and hyperkeratinization of the sebaceous ducts

7 Ultra-violet ray is a safe adjuvant in therapy, having its effect on pustules but not on seborrhoea

8 Combination of various local and of general measures offers the best result in treatment.

9 The lesions of acne offer in many ways a serious handicap to their possessor and merit more attention than is given them by the physician

10 Early and proper treatment will usually prevent the formation of the more advanced and disfiguring lesions of acne

### NEURONE BLOCK FOR THE RELIEF OF PAIN\*

By GEORGE I. SWETLOW, M.D., F.A.C.P., BROOKLYN, N. Y.

THE following paper is a presentation of the results obtained in severe unyielding pain by means of neurone block. A brief description of the anatomical, physiological and pathological bases upon which each of the various types of cases were treated, will be made. Instead of presenting individual case reports, summarized group reports will be made. The relief obtained is so satisfactory that its use as a therapeutic measure may be highly recommended. The following are the diseases in which pain as a symptom was treated:

- 1 Cardiac Pain
- 2 Tabes with Gastric Crises
- 3 Laryngeal Tuberculosis
- 4 Tuberculosis of the Pleura
- 5 Neoplasm of Lung, Pleura, and Superior Maxilla
- 6 Sciatica

The value of alcohol in neurone block depends upon the fact that a Wallerian degeneration is produced in the nerve, thus obstructing the conduction of pain impulses from the site of its production to the sphere of the consciousness. The alcohol destroys mostly the unmyelinated fibres and their somae. The latter are the small bodies found in the groups of cells making up the dorsal root ganglia. These cells and their unmyelinated fibres are the ones that convey the pain impulses (protopathic).

*Cardiac Pain*—The surgical procedure for the mitigation of severe unyielding pain in cardiac disease, attempts to eliminate the pathway along which the painful stimuli are passing. These impulses must enter the spinal cord in order to reach the thalamus. However, before entering the spinal cord these impulses must traverse the spinal root ganglia. On account of the meagre anatomical and physiological data as many as

\* Read before the New York State Medical Society, March 30 1926

eight different surgical procedures have been devised for the alleviation of the pain. The results obtained by these methods were so poor or indifferent and the mortality and morbidity so alarming that they called forth a sharp rebuke from Sir James MacKenzie in a rather recent issue of the *Lancet*. Jonesco showed graphically the dangers encountered because of an inadequate knowledge of the physiology of the cervical sympathetic system.

The use of alcohol injected paravertebrally into the dorsal root ganglia is suggested as a rational and safe procedure for the assuagement of cardiac pain.

The results can be briefly summarized as follows:

- 1 Eight patients suffering from attack of severe precordial pain, were treated by paravertebral injections of alcohol. Satisfactory relief was secured in every instance.

- 2 The alleviation of the pain following a single injection has usually lasted several months. One patient, who was reinjected after several months of relief, has again been made comfortable for a period of several months. This freedom from pain is still enjoyed.

- 3 No complications were encountered nor were there any serious after effects.

- 4 The procedure is simple and is based upon definite neurophysiological facts.

#### *Gastric Crises*

The operative treatment for gastric crises depends upon the following anatomical, physiological and pathological bases. Irritative processes, going on in the sensory sympathetic fibres of the stomach, enter the coeliac plexus. From this latter structure the stimuli pass into the dorsal root ganglia via the splanchnic nerves. After reaching the root ganglia, the impulses enter the spinal cord on their way to the sensorium. These anatomical and physiological observations suggested the idea that if the posterior roots were severed, the painful stimuli in their course to the spinal cord would be intercepted. Following along this line of reasoning, Forster and Moskowitz in 1911 practiced posterior rhizotomy. A perusal of the results obtained gave ample evidences of many brilliant results. However the failures according to the former surgeon, rose to fifty percent and the mortality reached as high a figure as sixteen percent. Indeed, many of the patients experienced relief for as long a period as one and one-half years. Purves Stuart advanced the suggestion, that the failures were caused by the fact that the remaining central stumps continued to convey painful influences. Attempting to eliminate these influences as a cause for failure, Sicard advised excision or avulsion of the root ganglia. The operation is extensive, severing the root segments from the fifth to the eleventh dorsal segments on one or

both sides. However, with the injection of alcohol paravertebrally, many advantages are obtained.

- 1 A rapid and minor operation, with little or no pain is substituted for a long and serious procedure.

- 2 An operation with no mortality replaces one with a mortality of sixteen percent.

- 3 The patient is discharged from the hospital at a maximum of 4-5 days.

- 4 The alcohol produces not only a degenerative effect on the dorsal roots and the sympathetic afferent unmyelinated fibres in the sympathetic chain, but also seeps up to the dorsal root ganglia, producing by chemical means what Sicard suggested should be done surgically.

A careful choice of the cases and a frank explanation to the patient of the results expected are necessary. The relationship of the symptoms found to the results expected is important. One group of cases complain only of severe constricting pain, another group complain of constricting pain together with nausea and vomiting, another group have no pain but complain only of nausea and vomiting. The first group is most ideal for treatment. It indicates that all the impulses are passing up through the dorsal roots and therefore alcohol block should mitigate the condition.

The second group is interesting. The impulses of pain which enter through the dorsal roots into the spinal cord pass up to the medulla, and, by stimulating the pneumogastric centre, produce secondarily nausea and vomiting. However some of the patients may also have the pneumogastric nerve itself irritated. This irritation alone can produce nausea and vomiting. As a result, the following may ensue after paravertebral block. The pain is usually relieved in all of the cases treated.

The nausea and vomiting may be completely relieved. In other cases the nausea may persist while the vomiting disappear. On the other hand, if the nausea and vomiting are due to vagal irritation no alleviation of the symptoms will be accomplished. At present we have no clinical method which would help us differentiate between vagal irritation and medullary stimulation secondary to irritation of the dorsal roots. The third group is characterized by nausea and vomiting alone. These cases are the least favorable. They are usually due to vagal irritation. We ought, however, to give these patients an opportunity by blocking the dorsal roots. Possibly some or most of the impulses may be passing through the dorsal roots and some relief would ensue. Six cases, typifying the various groups described, have been blocked with alcohol. The relief in the favorable groups of cases has persisted for several weeks to several months. At present they are still comfortable. If the pain should recur, another injection would be indicated after the irritable roots had been delineated.

### *Laryngeal Tuberculosis*

An understanding of the anatomical course of the superior laryngeal nerve and the structures supplied is essential for the success of the technique. The superior laryngeal nerve arises from the lower ganglion of the vagus. It runs downward and inward beneath both of the carotid arteries towards the superior horn of the thyroid cartilage. About one centimetre in front of and a little below the cornu of the hyoid bone, the nerve divides into an internal and external branch. The internal branch enters the larynx by piercing the thyrohyoid membrane. It supplies the mucous membrane of the base of the tongue, epiglottis, and larynx. The ganglion of the trunk from which the superior laryngeal nerve arises, is in anatomic connection with the upper ganglion of the vagus, which gives off an auricular branch. The auricular branch, after leaving the upper ganglion, courses along the inner surface of the facial canal and terminates between the mastoid process and the external auditory meatus. The nerve supplies the skin of the posterior part of the auricle and the posterior inferior portion of the external auditory canal.

The aim is to introduce a 65 percent to 75 percent solution of alcohol into the superior laryngeal nerve as it passes below the cornu of the hyoid bone. The sole indication we have that the nerve has been reached by the needle is the appearance of a sharp pain in the ear on the same side that the nerve is struck. Only then is the alcohol introduced. The amount injected varies from 1cc to 2cc.

### *Pleuritic Pain in Pulmonary Tuberculosis*

Six cases are reported of an apparently new application of alcoholic injections into nerve tissue for the control of severe thoracic pain caused by pleuritic involvement in pulmonary tuberculosis.

The following is a brief resume of the anatomical, physiological and pathological premises upon which the neurone blocking is based. The sensory nerve supply of the pleura is through the sympathetic system. The pain bearing sympathetic fibres from the upper parietal costal pleura arborize about cells in the dorsal root ganglia. The extent of this arborization is from the first to the sixth dorsal root ganglia. The lower costal parietal pleura as well as in the rim of the diaphragm sends its afferent impulses to the sixth to the twelfth dorsal root ganglia. Therefore, disease in the costal parietal pleura will transfer its effects in the form of pain to the chest wall. The site of reference will depend upon the intercostal nerves involved.

The aim of the technical procedure is to introduce an 85 percent solution of alcohol into or about both sympathetic fibres entering the root

ganglia and the dorsal root ganglia. The ganglia chosen for block are those which are receiving the maximum pain stimuli from the diseased pleura. These are found by careful sensory examination delineating the zones of hyperalgesia, hyperesthesia and hyperthermalgesia on the skin surfaces. These zones of hyperirritability indicate that the cell bodies supplying the sensitive skin segments are being bombarded by pain stimuli.

### *Neoplasm of Lung, Pleura and Superior Maxilla*

The control of pain in malignant diseases has always been one of great concern to the attending physician. The incessant employment of morphine in the care of these patients has serious disadvantages which may be summed up as follows:

- 1 Small doses of morphine afford little relief.
- 2 The perpetual use of morphine quickly raises the tolerance to the drug. As a result even large doses often fail to ameliorate the pain.
- 3 Morphine even in small doses may actually hasten death in the extremely weak and debilitated patients.
- 4 The drug so dulls the intellect that both the family and the patient are denied even the companionship of the last days.
- 5 Opiates are especially dangerous in diseases of the lungs for they greatly reduce the cough reflex. As a result the secretions are often brought as far as the bifurcation of the bronchi and are dropped back into an unaffected area. Thus a terminal pneumonia is produced.

Two cases in which the pleura was encroached upon by a malignant growth, were treated upon the following principles:

The upper six intercostal nerves supply the upper parietal costal pleura. The lower six send their intercostal fibres to the lower parietal costal pleura as well as the parietal pleura of the diaphragm. Disease, therefore, in the costal parietal pleura will convey its effects in the form of pain to the chest wall. The site of reference will depend upon the intercostal nerve impinged. With the blocking of the nerves supplying the diseased pleura pain stimuli would be prevented from reaching the sensorium.

One patient with a carcinoma of the tongue with metastasis and extensions to the floor of the mouth and the neck was injected because of the severe pain. The following anatomical and physiological facts were the basis upon which this patient was treated. The inferior maxillary nerve, a branch of the trigeminal, has both sensory and motor components. The sensory fibres arise from the lower anterior portion of the Gasserian ganglion and supply the skin over the side of the head, the auricle of the ear, part of the external auditory canal, the lower portion of the face and lip, the mucous membrane of the mouth,

the tongue, the lower teeth and gums, salivary glands and the temporo-mandibular articulation. The mandibular nerve enters greatly into the supply of the salivary glands. The parotid gland is supplied in part by the sensory fibres of the mandibular nerve through the auriculotemporal branch. The submaxillary and sublingual glands are supplied to a great extent by the lingual nerve, the large branch of the mandibular nerve.

### Sciatica

After a careful neurologic examination has been made, ruling out such conditions as tabes dorsalis, spinal cord tumor and hip joint disease, consideration for the symptomatic relief of the pain is in order. To attempt to relieve the pain in the presence of the above diseases would, if successful, be a pernicious result. It would mask the symptoms of the disease and might create great confusion in the pathway of a more basic and radical treatment. Under the general term of Sciatica I will also include the greater group classified under the term of Lumbar-Sacral Radiculitis. A review of the various methods used, leads one to the conclusion that much is left to be desired in the way of therapy. The following are some of the means employed—all forms of analgesics, counter irritation, hydrotherapy, hot packs, mud baths, spray douches, hot-air treatment and massage. The results obtained were so unsatisfactory by these methods that direct treatment to the nerve itself was considered and tried. Drugs having a degenerative action on the nerve tissue, i.e. carbolic acid, osmic acid, salicylic acid and alcohol are contra-indicated. Many sad results have ensued from the degenerating effects on a mixed nerve like the sciatic nerve. In a recent article Dr. Israel Straus of New York and William Ott of Rochester, Minnesota reported a fairly large series of cases in which they injected saline and novocaine into the epidural space. The results obtained showed that the patients were relieved for many months and in some cases permanently. In my own series similar results, exceedingly gratifying at times, were also obtained. This method is to be highly recommended.

*Technique* The patient is placed flat with a

pillow under the abdomen. The operator stands on the left side of the patient. With the left hand the coccyx is palpated. The finger is then passed up, palpating lightly, to a point where the coccyx meets the sacrum. At this junction a triangular space is felt with the apex pointing upward and the base downward. The sides of the triangle are made up by the sacral cornu. A lumbar puncture needle, with the bevel turned up is introduced into the centre of the triangle at about an angle of  $25^{\circ}$  to the skin. The needle is introduced until the anterior wall of the canal is reached. The needle is then withdrawn about two or three millimetres and introduced about six to eight centimetres at an angle of  $40^{\circ}$  to the spine. Before injecting the solution the stylet is removed to ascertain if any cerebral spinal fluid flows out. If cerebral spinal fluid is obtained the needle is withdrawn until the flow ceases. The presence of this fluid indicates that the needle has pierced the dural sac. If the injection was made under such circumstances, the saline and novocaine would be introduced in the spinal fluid. About sixty to seventy cubic centimetres of saline plus 125 grammes of novocaine are slowly introduced. This procedure is repeated about every four to six days. As many as four to eight injections may be necessary before considerable relief is secured. The fluid passes up the epidural space, bathing the roots and ganglia of the sciatic nerve. This fluid, as seen in cadavers, when methylene blue had been injected, may reach as high as the cervical region. The pain probably is relieved by the pressure effects of the saline on the roots of the nerve.

This paper presents the view that by means of neurone block with alcohol or saline, many of the intractable agonizing pains may be greatly ameliorated.

## "PILONIDAL SINUS"\*

By HYZER W JONES, M D, UTICA, N Y

**P**ILONIDAL SINUS, from "pilus," a hair, and "nidus," a nest, is the name applied to a condition in which there is a sinus leading to a hair lined cavity near the body surface. The most common site is the sacro-coccygeal region. The condition is usually the result of injury and the subsequent infection of a congenital cyst. In order to better understand the etiology, we will review briefly the description of "Dermoids" as given in Treves' "Text Book of Surgery." "Dermoids are tumors furnished with skin or mucous membrane, occurring in situations where these structures are not found under normal conditions. They only possess tissues and structures which normally belong to skin or mucous membrane."

"Treves" so-called "Sequestration Dermoids" give rise to the condition we are to consider. This type of dermoid arises in "detached or sequestered portions of surface epithelium, chiefly in places where during embryonic life, coalescence takes place between skin covered surfaces."

"The chief lines of coalescence in the trunk are situated in the mid-dorsal and mid-ventral regions, and extend from the external occipital protuberance backward along the spine through the perineum (and scrotum in the male), forwards to the epi-sternal notch. Dermoids may occur in any part of this extensive line."

"In the face, dermoids occur in connection with all the facial fissures, including the meso-palatine. These temporary fissures are liable to three defects directly associated with dermoids. They may fail to close, then such faults as hare-lip, cleft palate, macro-stoma, cleft sternum and spina bifida are the consequences, according to the seat of failure. The clefts may close imperfectly and leave complete or incomplete fistulae, which receive such names as post-anal or coccygeal dimples, sternal dimples, mandibular fistulae, and the like. A fissure may, to superficial appearance, close perfectly, but a tract of epithelium lies buried between the opposed and the coalescing surface, this buried scar and epithelium may grow and form a dermoid."

"Sequestration dermoids usually assume a cystic form. That is, the skin forms the wall of a central cavity which gradually enlarges as the individual grows and becomes occupied and distended by the shed epithelium, hair and products of the glands occupying the skin lining the cyst. Hair, sebaceous and sweat glands are usually present. Teeth are exces-

sively rare in this type of dermoids. Exceptionally, dermoids take the form of solid tumors, the skin clothing the interior, still more rarely, they are pedunculated." We have then the imperfectly closed cleft, with a sinus or fistula persisting from birth. The individual is probably unaware of its existence until injury sends him to a physician. There is another type in which there is a closed cyst. Injury with the subsequent inflammation may go on to suppuration. When drainage is established either spontaneously, or by the knife, a sinus persists. Then the condition remains quiescent until the individual's resistance is lowered or another injury results.

This is not a rare condition. I have observed twenty-two cases in the sacro-coccygeal region. All gave a history of trauma. The physical examination disclosed a red, boggy swelling with or without fluctuation and a sinus usually above the anus, rarely a little to one side. Below the swelling, between it and the anus may be observed one or more post-anal or coccygeal dimples, always in the median line. All the cases I have seen here were in individuals of the fat, chunky type, this may be just a coincidence. Not one was aware of any congenital condition or abnormality. All were sure they had a boil or an abscess and some were convinced only with great difficulty that a trip to the hospital was necessary to affect a cure.

The following case histories may be of interest.

Case No 1. A young man, age 25, was boarding a train to leave a picnic ground. He climbed on the last coach as the train pulled out. He was assisted in boarding the train by a man further back in the line who applied the toe of his boot to my patient's sacro-coccygeal region, at the same time executing a forward and upward movement. This patient said there was standing room only in the train, and he didn't care to sit down anyway. Two days later he was treated by a physician who used the lance to the great relief of the patient.

Three years afterward he came to me, saying that he had another boil on his rectum. He had had a boil every six months since his injury three years before, but had not seen a physician since the first time. Poultices were applied for two or three days and the trouble was relieved. Examination revealed a mass 5 cm in diameter in the fold between the buttocks and 7 cm above the anus. There was a discharging sinus at the lower part of the swelling. Between the swelling and the anus, there were two coccygeal dimples, neither of

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y May 11, 1927

which could be entered with a probe. An elliptical incision which extended down to the sacrum was required to lift out the whole infected area. On section it proved to be a sinus with considerable matted hair, pus and epithelial debris. Ten days in the hospital were required to clean up the wound, then recovery was uneventful.

Case No. 2. A woman, 35 years of age, was wading in a brook with some of her friends. She lost her footing and sat down straddling a sharp stone. I saw her two days later, when she was sure she had an abscess on her rectum. There was a red, tender fluctuating mass about 4 cm. in diameter directly over the coccyx. Below this mass was a tell-tale dimple in a fold between the buttocks. The opening did not admit a probe. Resection of the mass revealed a sac lined with skin and filled with pus and hair. Recovery was uneventful.

Case No. 3. A man, age 38, slipped on an icy step and fell, striking heavily on his coccyx. I saw him next day. Heat locally had relieved the pain, but he was still very sore. Examination showed the typical dimple with the red area above. Two days afterward, I advised his removal to the hospital. This he refused, simply saying he wanted the boil opened. Explanation availed nothing, so I opened the mass from the dimple to the upper extremity. After two weeks' drainage, he was well for six months, when I saw him again. There was a small sinus and a mass fully as large as the one he had at the time of the original injury. This mass was red, boggy and very tender. This time he con-

sented to hospital treatment and the mass was resected under a general anesthetic. This also proved to be a nest of hair.

The histories could be continued until twenty-two had been covered. In each case there was a history of trauma. Nearly every patient thought he had a boil or abscess which would disappear once it was incised. In the operated cases, it was necessary to go down to the sacrum to remove all traces of the skin lining, the wall of the sinus. In each case the mass was above the anus and posterior to the sacrum and coccyx. One was a case which had been treated as an anal fistula. The sac had been made to communicate with the rectum by an incision which severed the sphincter-ani. The true nature of the trouble was discovered three months later. This patient made a much slower recovery than the others, but has been entirely well after four years. In each case there was no doubt in the mind of the patient that simple incision would cure the trouble. Six of the cases I have seen have not submitted to the radical operation. They prefer to be incised at intervals from three to six months. One case I have opened only twice in three years.

The etiology then is, briefly, a congenital malformation which is brought to the patient's attention as the result of trauma. The symptoms are those of any localized pus collection. The diagnosis is concerned chiefly with differentiating the condition from anal fistula, ischio-rectal abscess, and osteomyelitis of the sacrum and coccyx. Treatment consists of radical excision of the whole tract. The prognosis is good where this treatment is followed.

## TEMPERAMENT IN PUBLIC HEALTH WORK

Most physicians have a conscientious feeling of their duty to practice public health and preventive medicine, but their various temperaments often lead them to apparently contradictory conclusions. There are conservative physicians who give advice to public health workers grudgingly and only when it is sought. The radical physicians do not wait to be asked to give advice to public health workers, but they seek opportunities to impress their views on others.

When physicians act as individuals, the con-

servatives may not agree with the radicals regarding the methods of accomplishing a common object. But New York State has taken the advanced ground that the medical societies of the state and counties shall assume the leadership in the practice of public health and civic medicine, and shall act through committees representing men of all temperaments. When doctors wish to attain a common goal they will find the ways to reach it, even though some individuals may insist on travelling a different road from that of the majority.

## THE COUNTY HEALTH DEPARTMENT AND ITS RELATION TO PHYSICIANS

If a county medical society had a paid field worker, what would he do? His principal duties would be to make arrangements for the practice of public health and civic medicine by the county medical society

He would conduct a campaign for educating the public, and would be in close touch with the editors and reporters of the local papers in order to supply them with medical news

He would make the arrangements for lectures on medical topics to be given by physicians, nurses and other public health workers

He would plan demonstrations and clinics in prenatal examinations, child welfare, the examinations of school children and the periodic examinations of adults

He would secure teachers in postgraduate courses for the physicians of his county

He would attend the meetings of the staffs of the hospitals of his county, and would assist the physicians in preparing their cases for report at the meetings

He would assist in tuberculosis clinics, and help the public health nurses to deal with difficult cases

He would attend meetings of his county boards of supervisors and the boards of health of the towns and villages, and would inform their members regarding the attitude of physicians in the matters that come before them

He would help the officers of his county society to plan their meetings and to secure speakers

He would represent his society in all other

activities which are conducted by the society in distinction from individual physicians

These activities which one would assign to a field worker of a county medical society, if the society had one, are almost identical with those which a county health officer would perform (See this Journal, May 15, 1927, page 563) If a county health department were established, one of the greater activities of its health officer would be to make the arrangements by which the physicians of the county could perform their duties in public health and civic medicine. The health officer would plan for clinics in child welfare, for example, and would arrange with the local physicians to conduct them. He would act, primarily, for the benefit of the people, rather than the glorification of an organization. Physicians would welcome him as their field representative

While experience with county departments of health has shown that they are not always in harmony with physicians, yet the Medical Society of the State of New York has abundantly demonstrated that physicians can guide and direct all phases of the practice of public health and civic medicine if they wish to do so. The great majority of the nine hundred or more health officers of the local health departments are active in their county medical societies and represent their medical brethren in all phases of public health work. A great part of the duty of a county health officer would be to represent and assist the physicians in the discharge of their civic duties. The county health officer would be of direct benefit to every physician in the county

## TYPHOID FEVER IN MONTREAL

It is not the function of a medical journal to publish news which may reflect unfavorably upon any community. There is a widespread feeling that there should be no publicity regarding the existence of an epidemic, but this is an instance in which silence defeats its own object, for when news is suppressed, exaggerated rumors spring up and do far more harm than statements of the truth

It is also true that when the full truth is discovered and told, the health officials take preventive measures which are effective and which make the stricken community even safer than one in which no search is made for cases and no prevention is undertaken

The City of Montreal, Canada, has had an epidemic of typhoid fever for over four months, with 1,000 cases and 100 deaths per month. Information regarding its cause and course has been hard to obtain, and still more inefficient have been the measures for its control. But the suppression of information has resulted in

an investigation by the representatives of the United States Public Health Service after the Departments of Health of New York and other states had been unable to obtain the facts. An abstract of that report is printed on page 858 of this JOURNAL, together with the comments of the representatives of the Department of Health of New York State

It is extremely unlikely that a situation like that in Montreal could arise anywhere in New York State owing to the existence of four preventive measures

- 1 Publicity of facts
- 2 The cooperation of physicians
- 3 The maintenance of efficient machinery for investigation and control
- 4 The quick application of all the forces for prevention

Health conditions in New York stand out with the greater credit when they are contrasted with those in its neighboring Canadian province.

## RABIES

Rabies is becoming increasingly prevalent in the eastern part of New York State, but boards of health make only sporadic efforts for its prevention. The great source of rabies infection is the army of stray dogs from which the kindest household pet may acquire an infection during a run of a block. Complete isolation of a healthy dog is well nigh impossible, and preventive inoculations are of doubtful efficiency although they produce some degree of immunization.

The most effective measure of prevention is the destruction of stray dogs, yet it is strange how people will claim an impounded dog, but will deny its ownership when the tax collector appears.

An element in the spread of rabies is the

breed of the dogs which run the streets. The style is now to own a "One man" dog, such as the police or the airdale. These dogs are friendly to one person or family only, and are quarrelsome with all other persons and with other dogs. When they begin to be sick, they have a tendency to snarl and bite to a far greater extent than the terrier or hound, which makes friends with everybody.

The official on whom rests the greatest part of the burden of the control of rabies is the dog catcher. He is efficient in direct proportion to the support which he receives from office holders and the public.

The prevention of rabies is an example of a public health problem which must be handled principally by laymen.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*Medical Inspection of School Children*—Twenty-five years ago the medical inspection of school children was well established in New York City, but the service was confined largely to practice against contagious diseases. This Journal for August, 1902, contains an article on the subject by Dr. F. W. Loughran, who says—

"It would seem that while the daily medical inspection of schools for the detection of disease is the result of scientific knowledge and research, it would be comparatively easy to have it introduced into all our communities, and yet from its inception it has met with manifold difficulties, not only from the ignorance of municipal authorities, not only from objections of the parent, but by many obstacles cast in the way by physicians of reputable standing.

"It is not necessary for me to go into figures to prove the efficacy of this system, though I might cite a few cases. A primary school of forty students had fourteen cases of diphtheria in eighteen days, all from one room. Of the fourteen cases, seven were discovered by a medical school inspector and three of these only by culture. All suspicious cases were dismissed from school and recommended to the care of their family physician. The next morning every child was examined and many cultures taken. The school was then dismissed from Thursday until the following Monday, and the rooms disinfected and cleaned. For ten days after his return the throat of every pupil was examined by a medical school inspector, when the children first assembled in the morning, and

no pupil who had been absent with any suspicious symptoms was allowed to return until it was proved by negative culture that there could be no danger. As a result of this measure not a single case of diphtheria resulted, beyond those known to have been infected at the time the epidemic was discovered."

Searching for contacts was then a new procedure, and Dr. Loughran says—

"The best results were obtained by securing the absence list of the school in which a case of contagious disease had occurred, and visiting the absent children to learn the cause. Eighty-five families with scarlet fever and diphtheria were visited and showed fifteen cases of scarlet fever and nineteen cases of diphtheria, thirty-four cases out of eighty-five in which the first case in the family was a school child. It was in the district reporting the largest number of cases of scarlet fever that the connection with the schools was best marked. The inspector reported that in his experience any severe outbreak had always come from the schools. The statistics seem to show that many cases of diphtheria went unnoticed, and the same was true in the instance of scarlet fever."

Fumigation was still practiced, for Dr. Loughran wrote—

"After the necessary disinfection and fumigation of the rooms in which there has been an infectious or contagious disease, postal cards will be mailed by the Division of Contagious Diseases, notifying the proper schools that it is safe to readmit the child or children living in those rooms."

# MEDICAL PROGRESS

**Drowning Accidents and Perforated Drum-head**—E Schlitter of Basle gives a monographic consideration of this interesting and seasonal subject. The author is attached to the local University clinic for otolaryngology and his authorities are chiefly colleagues. From the earliest times there have been mysterious deaths by drowning of good swimmers in which all of the well known causes of incapacity preceding drowning could be excluded. Certain of these have been explained by the status thymicolymphaticus, but autopsy may exclude this possibility. The association with drumhead perforation was first surmised by Lucae in 1885, by whom the suggestion was made that water entering the tympanum caused optic vertigo from disturbed pressure conditions and lead thereby to drowning. In 1899 Danziger revived the subject. In 1906, however, Parauy seems to have shown that not heightened pressure but a caloric factor is decisive. Swimmers with perforation have been known to complain of sudden vertigo but were able to fight it off or were rescued, but the great frequency of perforation with the small percentage of drownings in such subjects has always been a stumbling block to theorists. It is evident that there should be a systematic study of the drowned for perforation, and the author gives a technique for such examination on the cadaver and for special autopsy procedure for obtaining specimens for microscopic study. It is, of course, as essential to discover how the average subject with perforation escapes drowning as to determine the mechanism by which death results. These cases have an important forensic bearing—for example, supposed suicidal drowning might be shown to have been accidental.—*Schweizerische medizinische Wochenschrift*, June 11, 1927

**Treatment of Scintillating Scotoma**—Professor F Penzoldt of the University of Erlangen gives an account of a case of this disorder in his own person. The author runs naturally from one to three attacks monthly and sometimes shows as a sort of equivalent a vascular spasm of the fingers followed by headache of a migrainoid type. He is also a sufferer from ordinary migraine, but in his case the two affections seem quite dissociated, pursuing independent courses. The scotoma is at times in the form of colored flower-like spectra. In regard to treatment the author has never been able to cut short the scotoma but has been able to prevent the following headache by taking acetanilid promptly, while acetylsalicylic acid,

amidopyrine, acetphenetidin, etc., all have some power in this direction. A long series of preventive measures is enumerated, which should vary with the individual and which, if enforced strictly, might be worse than the disease. Here belong avoidance of overexertion, of constipation, of excesses at the table, etc. The only drug which holds out any hope appears to be quinine muriate, in doses of four grains four times daily. One should persist in the treatment even if the attacks continue. It may be necessary to take as much as one ounce before the desired effect is obtained, although this result has been seen after 150 grains only. One cannot speak of a radical or even a clinical cure, but the patient may secure some months of freedom from attacks. Nevertheless the author makes the statement that there may be spontaneous remissions of months' duration so that the result, to count, must be superior in duration to these latent periods. The treatment can be begun anew after the attacks reappear.—*Muenchener medizinische Wochenschrift*, April 22, 1927

**Tellurium in the Treatment of Syphilis**—Fournier, Levaditi, and Guénot have treated 40 cases of this disease at different periods with metallic tellurium and three salts of the metal given by injection, and have reached the conclusion that the treatment is powerfully efficacious, provided the amount is sufficient and the administration massive. The action is not so prompt as that of the arsenicals and bismuth, and some unpleasant by-effects have been noted which militate against pushing the remedy. These effects can be minimized by reducing the dose, but the action of the small dose, while satisfactory from the clinical standpoint, does not show a parallel effect on the Wassermann reaction. Moreover relapses are not uncommon after a course of treatment. Combinations of tellurium with arsenicals and bismuth do not offer any advantage. The chief task of the future is to find a way to obviate the drawbacks of the metal, in which case the valuable antisyphilitic power which it undoubtedly possesses may be utilized. The accidents and inconveniences are discussed at length. The exposed parts—face and hands—may assume a bluish tint and in many cases, especially in brunettes, the hair is bleached although very incompletely—where the hair is shortest, as on the temples and in the nuchal region, but not for its entire length when it is long. The odor of garlic on the breath is pronounced, which is hardly noted by the patient, but is very disagreeable to his entourage and often persists long after the

treatment is over. A few patients showed a marked resistance to the remedy, as occurs in the case of other antisymphilitic drugs. It may be possible to incorporate the metal in a synthetic which shall be without its drawbacks—*Annales de l'Institut Pasteur*, April, 1927

**Arsphenamine Treatment and Metasyphilis**—L. Spitzer notes that arsphenamine has now been on trial for about 20 years, and the present generation of medical men comprises many who recall the astounding action of the drug which in some cases appeared to do in a few weeks or months what had hitherto required years. Numerous technical difficulties and accidents could not slow up the great advance of the new treatment. Various questions, however, demand answer and one is, does this treatment tend to prevent tabes and paresis? The authors material nominally controlled amounts to around 5,000 cases which date back to 1906. Of this number comparatively few were completely controlled over the entire observation period, the total being 406 or considerably under ten percent. The cases of metasyphilis amounted to 134 but the author goes outside of the nervous system under the term metasyphilis, by including aortitis, disease of the labyrinth, and other late sequelae. There were 53 cases of tabes and 28 of paresis, making 81 of metasyphilis in the usual acceptation of the term. Analysis shows that to prevent metasyphilis arsphenamine must be given as early as possible,—that is to say during the period of the primary lesion. Given after this period, even when conjoined with mercury, the drug cannot prevent the development of metasyphilis. There is even the likelihood that vigorous treatment begun too late may cause metasyphilis to appear precociously. In these cases the author made use of arsphenamine and mercury. An instance is given which shows that even when this treatment is begun in the primary stage there is no absolute guarantee of prevention of metasyphilis. In a married pair vigorous treatment was begun and maintained from the time of the primary lesion, but the husband developed tabes in the fourth year of the disease while the wife in the same period suffered a hemiplegia. The author shows by statistics that vascular disease is very commonly associated with metasyphilis of the nervous system—*Muenchener medizinische Wochenschrift*, April 15, 1927

**"Benign" Smallpox (Variola Nova)**—Prof Naegeli of Zürich mentions three new types of disease which have appeared in Switzerland during the past decade, of which the first two are the influenza pandemic and lethargic encephalitis. The benign form of variola appeared suddenly in the Canton of Zürich in 1921, and of 1,100 patients seen in the author's service but two perished. At the same time ordinary smallpox with

a mortality of 15 percent prevailed in a small way in Basle. In the mild form the lesions tended to be sparse and abortive, the secondary pustulation fever was absent as a rule, and there were none of the serious complications of variola. The blood counts which characterize the latter disease were absent. Naturally there was doubt that the disease was smallpox, but the Paul test on the rabbit cornea and the allergy test were positive, and vaccination rapidly checked the spread of the disease. The probability is that the new affection was of the type (alastrim) previously seen in Brazil, the West Indies, the United States, England and elsewhere. Although possibly due to a special strain of virus the fear is always present that this mild form may be able to transpose itself under unknown conditions to the severe type. The author would for the present term the new expression of disease *variola nova* for we cannot be sure yet that we have to do with a varioloid or a modified smallpox. Over a century ago epidemics of mild smallpox were reported in the Canton of Zürich by Fehr, but a study of his material shows the outbreak was much more severe than variola nova, for many severe cases and some fatalities developed—*Schweizerische medizinische Wochenschrift*, April 9, 1927

**The "Perna Disease" (Chloric Acne)**—This affection is discussed at length by Dr Teleky in the *Klinische Wochenschrift*, April 30, 1927. Contrary to what would be assumed, the term perna disease is not an eponymic, perna being merely a sort of code contraction of perchlor-naphthalin, the chlorinated naphthalin employed extensively in the preparation of gas masks. The women workers on the latter during the war suffered considerably from chloric acne and the term in question was introduced in 1918. At the end of the war in the same year the new disease dropped out of sight along with its name. Chloric acne was known long before this period and in 1899 a form was described which developed in chlorine works in connection with the electrolytic decomposition of some of the salts which contain the element. Originally classed with other halogen acnes (bromine, iodine), it was later ranked with the tar acnes and pronounced a nonspecific affection. Recently perchlor-naphthalin has been used in the mining industry, paper soaked in it being employed in the insulation of wire, and 170 workers with this substance developed the disease, although only 70 to a moderate or severe degree. It was found that practically none escaped who had worked for more than four weeks with the chemical in question. Aside from the name, the condition is of interest only to those interested in industrial medicine.

**Intolerance to Sugar as a Factor in the Production of Some Dermatoses**—G. Gordon

Campbell, writing in the *British Journal of Dermatology and Syphilis*, May 1927, xxxix, 5, shows that the temporary rise in blood sugar which occurs in those who exhibit intolerance to sugar is also concerned in the production of skin lesions, mainly of the dermatitis type, and that a diet restricted as regards carbohydrates, may bring about a cure of these lesions when other methods have failed. Sugar may become injurious to the organism, especially after middle life, through the inability of the digestive system to handle it, then, if taken in too large quantities, it raises the blood sugar above the normal limits. Persons showing this phenomenon are not diabetics, they are simply intolerant to sugar. In most of the author's cases there was nothing that would lead one to suspect sugar intolerance as a cause, he has learned to depend upon the history of the case as pointing in that direction. This is the development of an intractable dermatitis in an individual past middle life, who has made no change in his habits or occupation, and who has previously been entirely free from such attacks. In some cases the dermatitis is caused apparently by irritants to which the individual has long been accustomed to expose himself without any untoward effects, for example, the surgeon found that certain antiseptics which he had used for years with impunity produced a dermatitis. In some cases limited to the axillæ and about the genitals, a high sugar content of the sweat was probably the actual cause of the disease. Of 31 cases showing intolerance to sugar 18 remained under observation until the skin lesions had entirely disappeared, the time varying from one to six months. Relapse of the skin conditions was noted when sugar was again taken in the diet, and a return to a sugar-free diet was followed by complete disappearance of the eruption. In many of these patients a sugar-free diet had resulted in a marked improvement in general health and an increased capacity for work.

#### Sciatic Pains and Their Differentiation—

Frederick P. Moersch, writing in *The Military Surgeon* for May, 1927, lx, 5, classifies sciatic pains into two major groups: sciatic neuritis (a clinical entity) and symptomatic sciatica (erroneously called sciatica) indicative of a pathological process directly or indirectly affecting the sciatic nerve. For purposes of clinical discussion the latter group is divided into three subgroups: (1) sciatic neuralgia (sciatica), (2) peripheral sciatica, and (3) radicular sciatica. These groups should be separated whenever possible. Sciatic neuritis, though usually gradual in onset, may develop in a few days. In the late course of the disease spontaneous pain is usually very slight, in marked contradistinction to sciatic neuralgia in which the pain persists for a long time. There are three outstanding objective findings in sciatic neuritis: reflex, sensory, and motor disturbances.

The sensory disturbance is peripheral in distribution and distinguishes the affection from a central disturbance in which the sensory disturbance is segmental in character. Contrary to the various types of neuralgia, sciatic neuritis rarely reaches a stage of complete recovery. Sciatic neuralgia runs a course of several months, even several years, without at any time showing definite objective signs, while a mild case of neuritis usually shows definite findings within a short time. Impairment in the gait and posture are marked symptoms, but paralysis does not occur. Under the term peripheral sciatica are cases which may fall into either of the foregoing groups, but because of the presence of unusual signs or lack of signs, cannot be clearly classified. In this group the pains may be the result of arthritis of the sacroiliac joint, of trauma, pressure, or inflammatory reactions, but frequently the cause can be determined only after a long period of observation. The objective manifestations range from entire absence of findings to extreme weakness, atrophy, and reflex disturbance. Radicular sciatic pains are usually the result of caudal lesions, or pressure on the caudal nerves. The neurological findings are, as a rule, central and not peripheral. In this group of cases examination of the spinal fluid is helpful. It is well known that anterior sacral tumors may exist for years under the diagnosis of sciatica. Many causes which are not specific for any group of cases must be considered as the possible source of trouble in every case: toxic and infectious conditions, muscular affections, bone lesions, lesions of the nerve and cord, vascular diseases, pelvic and abdominal diseases, and constitutional diseases. In every case of sciatic pain a careful history and a physical examination are paramount, a rectal examination also should form a part of the routine. Roentgenological studies should be made with care and interpreted with caution. If there is any doubt as to the cause the spinal fluid should be studied. Treatment must be directed to the cause. Injections in cases of neuritis should be avoided.

**The Prevention of Cancer—**The importance of chronic irritation as an exciting factor in the production of cancer is forcibly emphasized by James Ewing in an article in *Surgery, Gynecology and Obstetrics*, May, 1927, xlv, 5A. He asserts that the more carefully we investigate the doctrine of tissue predisposition, the less satisfactory it becomes. The hereditary tendency may be present to an extreme degree, but it rarely expresses itself unless extraneous factors are brought into action. Persons with a strong family tendency should take unusual precautions against the disease. The parasitic theory is untenable since it is not compatible with the known facts, cancer is not an entity but a great group of diseases of varied origin and course. It is in-

conceivable that one microorganism should be responsible for all of them. Intra-oral cancer is due to bad teeth, tobacco, and syphilis, in the order named. A large proportion of buccal cancers arise in tobacco users who have bad teeth, ill-fitting plates, and dental bridges. The public and the dental profession should be urged to take a lively interest in buccal cleanliness and sound dentistry for the avoidance of cancer. To combat buccal infections Ewing recommends the regular use of soap gargles. Cancer of the genitals in both sexes is nearly always traceable to forms of uncleanness. Cancer of the uterus is distinctly less frequent in Jewish women than in those of some other races. The general adoption of some form of circumcision might reduce the incidence of genital cancer in the male. In cancer of the skin predisposing factors are suppressed hair follicles, overdevelopment of sweat and sebaceous glands, and congenital pigmented moles. Persons with oily skins and a heavy growth of coarse hair should know that vigorous and frequent scrubbing with soap and water are required to rid the skin of accumulating secretions. Suspicious warts and pigmented moles in situations exposed to irritation should be removed. The incidence of cervical cancer would probably be diminished by insistent repair of cervical lesions following childbirth, and by periodic examinations during and after the childbearing age. Alcohol, tobacco, and the bolting of hot, irritating, imperfectly masticated food must be regarded as highly important in the causation of esophageal cancer. Gastric cancer is probably due to the habitual abuse of the stomach. No particular type of diet has any known influence on the incidence of cancer, but one may preach without limit moderation in all things, sane and simple living, and minute attention to the general hygiene of the organs. Clinical, anatomical, and experimental data indicate that stagnation of the secretions is a prime factor in the causation of chronic mastitis and mammary cancer. A tendency to chronic mastitis should be treated with the object of draining the breast, and the practice of early and abrupt weaning of infants should be scrutinized from the point of view of its probable relation to mammary cancer. The irritation of chronic constipation in relation to cancer of the rectum must not be disregarded. Ewing fears too much should not be expected from any effort, however extended, to acquaint the public with these facts and to get them to act upon them.

**Radium Carcinoma of the Thumb**—Although many cases of cancer due to prolonged exposure to  $\gamma$ -rays have been reported, practically none has been recorded which was the result of continued exposure to radium salts. For this reason,

Cecil P. G. Wakeley describes a case of radium carcinoma in a man, aged 65, who had handled radium salts since 1904. In 1913 he first noticed a little roughness of the hands and experienced a tingling sensation in the fingers. During the World War he handled a considerably greater amount of radium salts than usual, with the result that in 1916 his hands became discolored and his nails began to fissure and became very friable. In 1920 warts appeared, and in 1923 the skin of both hands was atrophic, thin, dry, and wrinkled with numerous small patches of lightish brown pigmentation on the dorsum of the digits. In 1923, a small wart was removed from the back of the third digit of the left hand, microscopically, this was found to consist of chronic inflammatory tissue together with early squamous cell carcinoma. The patient, against advice, persisted in his research, and came under observation again in May, 1924, with a large fungating growth of the right thumb. The thumb was amputated and the wound healed well. When the cancer did develop, it grew very rapidly. It is of interest that the patient's wife, who helped him with some of his radium work, died of carcinoma of the bladder.—*British Journal of Surgery*, April, 1927, xiv, 56.

**Cure of Radiologists' Cancer by Diathermic Coagulation**—H. Bordier relates the case of a constructor of apparatus who had been exposed for many years (since 1895) to small doses of roentgen rays, the parts exposed being the face, hands, and thorax, also the eyes. About 1907 he began to note the presence of small warts on the left hand and the following year lesions appeared on the eyes, but the author will not take time to narrate these and merely states that they finally yielded to diathermy. The left hand became the seat of a tumor which by 1914 had developed a fungating tendency, and after its removal in 1918 there was a recurrence in 1920 which was seated in the angle made by the first and second fingers, also extending upon the digits. The mass was ulcerated and discharged a fetid ichor. By 1926 the pains had become intolerable, both in the affected hand and the arm and it was proposed to amputate, but the author was called on to treat the mass by his method of diathermic coagulation which requires the use of a special bulbous electrode with an amperage varying between 150 and 400 with contact of 3 minutes. The pains at once ceased and after 15 days a large slough came away with complete cicatrization in 6 weeks. Some outlying portions of the mass which were seated on the two fingers were destroyed at a second seance.—*Acta Medica Scandinavica*, April 30, 1927.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE SUMMER VACATION.

It is hot, the dog days are upon us, it is time for rest and recreation. To the complicated, exacting and trying duties which daily befall the professional man, especially the physician, it is essential that he should bring to bear a clear mind, a fresh point of view and a steady hand.

As the writer more and more comprehends and increasingly appreciates the grave responsibilities, the nervous tasks, which are the lot of every busy doctor, the wonder to him is, not that so many of this great profession die in the very fullness of their powers and strength, but that any of them attain serene old age. Quietly making his rounds in the hospitals or his calls upon the sick at their homes, listening to the constant histories of pain and suffering, the worries and the fears of friends, supported only by his own fortitude and strong will, the doctor goes about his work painstakingly applying all the results of his study and his professional knowledge for the alleviation of pain and suffering for the benefit of mankind. Unheralded and unsung, oftentimes bitterly assailed and criticized, frequently misunderstood, the doctor plies his troubled way through life wherein mayhap the only award awaiting him is the possession of a quiet conscience and the consciousness of work well done.

Much has been said in criticism of the medical profession, its virtues go unclaimed.

It is, therefore, not only a privilege, but it is in a very real sense the duty of every physician to dedicate some part of his year

to recreation, rest and peace. Just now the woods, mountains and the pleasant beaches all are calling. We trust that by no member of this great profession will the call go unheard. In the hurried, hectic, troubled life of modern civilization there is all too small a place for contemplation and quiet, and yet it is in those rare moments that man finds himself and attains to those readjustments which the shocks of life so pressingly demand.

To every one of his medical friends, therefore, (and the writer now numbers these by the hundreds) a pleasant, recuperative, beneficial summer most heartily is wished. Out in the trout streams, in the forests, in and on the refreshing waters of the Atlantic, along the smooth white ribbons of road that now make the remotest corners of our land accessible, it is hoped that every doctor will seek and find the rest and recreation that he needs and to which he is so abundantly entitled.

Having carried as best he could, in court and in conference, the burden of his responsibilities, the writer himself has decided for a few weeks to get far away from the turmoils of the city, and has planned to spend the month of August upon a ranch in Wyoming. Here it is hoped that he will gain added strength for the duties of the coming year for the championship and espousal of the rights and the just causes of the medical profession, collectively and individually.

The year has been an exacting and a difficult one, and yet the countless acts of co-operation, sympathy and friendliness have lightened his task and filled him with a new appreciation of those whom he seeks to serve.

## SPIRAL FRACTURE OF HUMERUS—OPEN OPERATION

A physician had rendered professional services to a patient for a period of about five months and after many unsuccessful attempts to collect for said services, instituted an action against the patient. As quite frequently happens, the answer of the defendant contained a counterclaim of alleged malpractice. Here it was charged that the defendant had been engaged to attend and treat the plaintiff for a fractured arm, that his operation and treatment was so careless and negligent that the bone of said arm was caused and

allowed to over-ride and over-lap, the arm became shortened and the patient became permanently crippled and was obliged to and did expend large sums of money in procuring the services of other physicians and surgeons to correct the deformity.

On August 21st the patient was brought to defendant's office, at which time his arm was in a sling with a weight attached at the elbow and was encased in a shield of plaster paris extending from the elbow to the shoulder. The patient

gave a history of having sustained a fracture of the humerus by falling when alighting from a taxi cab and striking his elbow on the sidewalk. He received treatment at a hospital where an X-ray was taken. The X-ray disclosed a spiral fracture of the humerus extending from about the middle down to the condyle with marked displacement of the fragments and separation of from three-eighths to one-half inch. The spiral fracture was about six or seven inches in length and the loose fragments were about four inches long. The examination of the arm made by the defendant disclosed that the same was bruised the entire length of the humerus and that the fragments were pulled downward by the anconeus muscle. After his examination of the arm and of the X-rays the physician advised an open operation to properly reduce the fracture. The treatment advised was acquiesced in by the patient, but he would not submit at that time as business matters required his attention, and he stated that he would communicate with the doctor when he was ready to submit to the operation. At this time the doctor told the patient that the history of his injury sounded improbable and that if he had fallen and struck his elbow as the patient had stated he would not have had a spiral fracture but rather a transverse fracture of the humerus.

At a visit about six weeks later the patient then stated that the fracture had occurred while he was doing a hand wrestle or twisting wrists with another person. To the doctor the fracture had all the appearance of having been caused by means of ju-jitsu, as the same evidenced the use of a twisting force upon the upper arm. On August 26th the patient advised that he was ready to submit to the operation. Arrangements were then made for him to enter a hospital. The doctor had two other physicians assisting him in the performance of the operation. The three physicians examined the arm prior to the operation. No nerve involvement was disclosed by the examination. In preparation for the operation the patient was placed upon the operating table on his left side, his body being braced with sandbags and his right arm on the operating table parallel to the axis of the body. An incision was started at the external condyle, carried up through the separation of the lateral head and longitudinal head of the triceps muscle, the incision being about six or seven inches in length. The muscles and intermuscular septum were separated with blunt instruments and fingers. The periosteum was found to be torn and shattered in various places.

The tearing of the periosteum was rendered extensive by reason of the piece of loose bone which was about four inches long and one inch wide at one point. An examination of the arm through the incision did not disclose any nerve involvement. In making the incision great care was exercised so as to prevent the severance or interference with any of the nerves and to carry

the incision upward and down under the muscular spiral nerve. Upon completion of the incision, the bone and fragments were cleansed, and blood clots and bruised and loose tissue removed. The humerus and fragments were then drilled and tied up with kangaroo tendons, the muscular spiral nerve being retracted from the field of operation. The bone appeared to be healthy although the surrounding tissue was discolored, bruised and anemic, which was probably caused by trauma at the time of fracture and by the length of time the arm had been neglected and not treated between the date of the reception of the fracture and the time of the operation, a period of about twelve days. The lacerated periosteum was united with chromic catgut. The muscles and fascia were united with twenty-day absorbent chromic catgut and the skin with three to ten-day absorbent light catgut. The kangaroo tendons were about forty-day absorbent tendons.

Upon completion of the operation the arm was painted with iodine, neutralized with alcohol and antiseptic dressings applied, the forearm being placed in a perpendicular position at about 45 degrees flexion. Two days after the operation X-rays were taken which disclosed that the fracture was in perfect apposition and there was perfect alignment. In about four days the patient objected to the position in which his arm had been placed and requested the doctor to place it laterally across his body. This the doctor advised against and told the patient that it might interfere with the progress of the repair of the arm. The patient, however, was insistent and stated that he would take all the responsibility for the change in position. The doctor then, assisted by the two physicians who assisted him at the operation, cut a piece from the posterior side of the cast, about six inches in length and three inches in width. He then with sterile dressing grasped the upper arm between the thumb and forefinger, supported the wrist with his left hand and rotated the humerus in the subglenoid cavity, placing the forearm in a lateral position horizontal to and across the body. In making this change of position the fracture and the elbow were not disturbed. After the change in the position of the arm the patient left the hospital on several occasions and went to his place of business, returning to the hospital. Seven days after the operation he was discharged from the hospital. While in the hospital he was seen daily by the physician and a general examination made of his condition and his temperature taken so as to determine the presence or absence of any infection. After leaving the hospital the patient visited the doctor at his office several times a week until the following November. On these visits examination was made and the portions of his body around the cast were cleansed with alcohol and care taken to prevent any abrasions by friction.

On September 10th further X-rays were taken, an examination of which showed a separation of

the fragments of about  $\frac{1}{8}$  of an inch near the condyle. The doctor felt that this separation was caused at the time of the change in position of the arm from the perpendicular to the horizontal. In order to overcome and correct the separation, the posterior portion of the cast at the elbow was removed and a wooden splint inserted over the sterile dressing.

In October, X-rays were again taken which showed about 1-16 of an inch separation. The callus formation and the healing process were good and the fragments in good position. The doctor advised the patient that due to the nature of the fracture the tearing of the periosteum and the bruised and anemic condition of the tissues, the callus would be slow in forming and that he would probably have to have the cast on for about ninety days. In the latter part of October the large cast over the body and arm was removed. Examination of the arm at the site of the fracture did not disclose any nerve impairment or atrophy of the muscles other than by non-usage. Tests were made to determine the ability of the patient to function the arm. Examination at this time also disclosed that there was perfect union of the incision, with no discharge from any part of the incision and no stitch abscesses. The arm was then cleansed with benzine and alcohol and tested for flexion and extension. The extension was about 170 degrees with a full 90 degree flexion. The arm was rebandaged with sterile dressings and a light cast applied, extending from the elbow to the shoulder and held in position by adhesive tape attached to the body above the shoulder and the arm below the elbow. No shortening of the arm was found at this time. When the large cast was removed the arm was massaged with oil and active and passive motion given. The small cast was

removed in the latter part of November. While this cast was on, the patient called at the doctor's office several times, when the arm was examined and massaged and active and passive motion given. At the time of removal of the small cast, on palpating the arm there was a feeling of solidness, showing good condition of the fractured bone. Tests were made by having the patient rotate, flex and extend the arm, and no impairment of function of the fingers, hand, wrist, elbow or shoulder was observed, the patient having complete use of the arm and no nerve involvement or atrophy of the muscles, except such atrophy as was due to non-usage while the arm was in the cast.

The light cast after being placed upon the arm was slit down so that it could be removed and examination made of the arm, and also massage, active and passive motion given.

The patient stated to various persons that the physician was the one who had saved his arm, and in the following March, while at the physician's home, the patient lifted with both his hands and arms a jar weighing about sixty pounds.

The patient, in his complaint against the physician, charged that by reason of the physician's negligence and carelessness in the treatment and reduction of the fracture, the patient's arm was shortened about one inch and that the function of the same was also impaired, thereby causing him permanent deformity and disability. This malpractice claim was asserted solely because the physician attempted to enforce the patient's obligation to compensate the physician for the value of the services which he had rendered.

During the pendency of the action this physician died, the action abating by reason of his death.

### ABRASION OF BREAST WHILE APPLYING BANDAGE

A woman about thirty years of age sought to recover damages for an infection of the breast claimed to be due to defendant's negligence while treating and bandaging a dislocated shoulder, it being charged that while applying the dressings, through the physician's negligence a safety pin lacerated the breast which later became infected.

This plaintiff, suffering from a dislocation of the right shoulder, came into the hospital where the defendant was in attendance. She was brought to the operating room and the preliminary care given her by a physician assisting the defendant.

An examination was made of her dislocation and a general anaesthesia administered to her and the dislocation reduced. The bandage was applied by the defendant's assistant.

The patient was next seen by the defendant at his office, two days later, and upon removal of the bandage he found a slight abrasion of the breast, the patient stating that at the time of the application of the bandage a safety pin had abraded the breast. When seen a week later the abrasion had entirely disappeared, the dislocated shoulder was in good condition, and the patient discharged from further care.

When the case came on for trial, the plaintiff not appearing to prosecute, the complaint was dismissed.

# NEWS NOTES

## THE ARMY MEDICAL FIELD SERVICE SCHOOL

The annual two weeks' course for Medical Reserve Officers of the United States Army was held on July 3-17 at Carlisle Barracks, Pennsylvania, and was attended by over 300 officers from the northeastern states. New York State was represented by 58 physicians, 15 dentists, 6 veterinarians, 12 medical administration officers, and 6 belonging to the Sanitary Corps. The Medical Administration Corps consists largely of pharmacists and clerks from medical supply houses, and their duty is the handling of the extensive medical supplies that an army needs. The Sanitary Corps includes such non-medical officers as sanitary engineers and laboratory technicians. All the various branches are coordinated under the command of a physician.

The basic unit of medical service to an army in the field is the Medical Regiment of a division of troops. With each fighting regiment has a medical service consisting of 7 physicians and 2 dentists. These officers are prepared to give first aid only, such as that which any physician is qualified to give in emergencies. The transportation and care of the seriously wounded and the sick belong to the division, which has a medical regiment of over 800 enlisted men and 69 officers under the command of a colonel who is a physician.

The instruction given at Carlisle is that which concerns the Medical Regiment of the Division, for the scope of its activities has no counterpart in civil life. The work done by officers with combat regiments is like that in private practice, and that in hospitals behind the fighting area is almost exactly like that in civil hospitals. But the work of the Medical Regiment of a division of troops differs from that in civil or industrial life. It is peculiar, in that medical service is not brought to the sick and wounded of an army in the field, but the incapacitated soldiers are transported to hospitals often for several miles in the rear. The peculiar work of the Medical Regiment is to transport the sick and wounded from the field to the hospital quickly, comfortably, and safely. This involves the application of first-aid dressings, the preparation of the patients for a journey of from five to ten miles, and carrying them on litters for a mile or more to places where the ambulances can reach them, and the maintenance of ambulance routes for taking patients back to the hospitals and bringing supplies into the combat zone. All these details are now standardized and sys-

tematized under the command of a medical colonel who is a member of the Staff of the Major-General in command of the Division, and has authority and responsibility equal to that of the commander of artillery or the quartermaster.

The Field Service School gave the Medical Reserve Officers a two-weeks' intensive training along the special lines that are peculiar to the Medical Regiment of the Division. The first week's work was largely explanatory, but that of the second week was practical. An actual problem was given, consisting of a battle staged over twenty-five square miles of territory extending for twenty miles northwest of Carlisle. The student officers were required to make a complete reconnaissance of the territory with the aid of U. S. Geological maps, and to familiarize themselves with the features of the land with special reference to roads, shelter, and water. The mornings were spent in automobiles making the reconnaissance, and the afternoons were given to the placing of the collecting and hospital stations, and establishing command posts at strategical points.

Each officer was required to write out the field order for the day. That of the first day was for a division which had met the enemy in an unexpected engagement. The order of the second day was for a prepared attack while that of the third day was for a withdrawal in the face of a hostile enemy. One may judge the importance of the work of the Medical Regiment when one realizes that about one-tenth of the men engaged in a battle will receive major wounds, and will require medical attention and transportation through the maze of marching troops' and trains of ammunition and supplies.

This was the fifth year of the Field Service School, and the instruction was on a higher plane than ever before. The Medical Officers came to camp and lived as units under the command and control of their own officers. The 302nd Medical Regiment, belonging to the 77th Division—that from Greater New York—was the largest group, and comprised of 31 men. Each officer in the unit was required to write the order which he would issue in actual combat. The first period of the morning was given to a critique of the orders written the previous afternoon.

The Medical Regiment of the Division has been created since the world war, and its func-

tions have been developed at the Field Service School, which is the "West Point" of the Medical Officers. Books on the functions of the Medical Regiment have been written by the Regular Army instructors stationed at Carlisle, and are the basis of the instruction at the Post, and of an extensive series of correspondence courses that are conducted by the Regular Army.

A six-weeks' field course for R O T C medical students was also going on at the same time with the course for Medical Officers, with about 500 in attendance. These lived in tents adjoining those of the Medical Officers. They were given basic training in the duties of the soldier, especially those points having a medical significance. They learned how to make

and carry their own packs, how to carry litters, to load ambulances, and how to set up hospital tents and handle the standard Army medical supplies. They also drilled with service rifles, and took part in a grand review in honor of General Summerall, who praised them for their soldierly bearing.

The Army Field Service School has an exceedingly important place in medical affairs of this country. It has trained a thousand medical men and two thousand medical students, and has prepared them to perform the duties which will devolve upon the medical profession if an emergency should occur. This body of trained men demonstrates that the medical and allied professions will be prepared to do their part in the next National emergency.

### THE TYPHOID EPIDEMIC IN MONTREAL

The July eleventh issue of *Health News*, the weekly official publication of the New York State Department of Health, contains the following article entitled "Authentic Information on the Montreal Typhoid Epidemic"—

#### EDITORIAL NOTE

Since about the middle of February a severe epidemic of typhoid fever has been prevailing in the city of Montreal, Canada, with a case incidence in proportion to population probably unprecedented by any other large city in the world within the present century. Up to the first of the present month information as to the cause of the outbreak, said to be milk-borne, was very unsatisfactory, notwithstanding efforts of the Commissioner of Health of this state and health officials of other states to ascertain the facts.

With the permission of the Deputy Minister of Health of Canada, the Surgeon General of the United States Public Health Service sent a board consisting of three medical officers and a sanitary engineer to Montreal for the purpose of securing epidemiological data and ascertaining what additional measures might be necessary for health officers to enforce in this country against the spread of typhoid fever from that city.

This board consisting of Dr. L. L. Lumsden, chairman, Drs. J. P. Leake and C. E. Waller, medical officers and H. R. Crohurst, sanitary engineer, began their survey in Montreal on June 18 and continued until June 29. Their conclusions and recommendations are in brief as follows:

#### CONCLUSIONS

"1 The typhoid fever epidemic in Montreal, Canada since February 15, 1927, was beyond

reasonable doubt caused by infection distributed in the output of milk from the plant of the Montreal Dairy Company, Ltd., in that city.

"2 Though contributory infection may have been introduced into the milk at one or more of the four stations or within the plant in Montreal, the preponderance of evidence is that the bulk of the infection was introduced into the milk at the farm sources and was enabled to multiply before the milk reached the city plant.

"3 Though it was barely possible for a very small proportion of whatever infection was in the milk to pass through the pasteurization machine without being heated long enough and at a high enough temperature to be destroyed, the preponderance of evidence is that a very considerable proportion of the infected milk was passed through and distributed from the plant without being subjected to pasteurization treatment.

"4 A large proportion of the milk which at the beginning of the epidemic was distributed through the dairy plant and which is now presumably being distributed through other plants or channels to consumers in Montreal and elsewhere is not now being officially controlled in such manner as to preclude its possible menace to the public health.

"5 Montreal is not yet a comparatively safe city for visitors, who are likely to be susceptible to typhoid fever infection.

"6 Milk and milk products derived from sources within the general vicinity of Montreal do not appear to be produced or processed under satisfactory sanitary conditions nor under official health supervision approaching adequacy.

### RECOMMENDATIONS

"1 That state and local health officials and other persons concerned be advised that Montreal is not now, from a typhoid fever standpoint, a comparatively safe city for tourists from the United States to visit and is not likely to be such for months yet to come, unless local health service in the city of Montreal and the vicinity thereof promptly is made much more nearly adequate than it now is

"2 That such steps as may be necessary be taken to encourage or bring about under proper official supervision radical improvement in sanitary conditions under which milk and milk products are produced, handled or processed in the city of Montreal or at any other place in the Province of Quebec within a radius of one hundred miles of the city of Montreal for export to the United States, and that such milk or milk products after reaching points to which shipped in this country and before being distributed to consumers be pasteurized or otherwise processed under official supervision so as to be rendered free from typhoid, tuberculosis or any other infection likely to endanger human health"

The use of milk and cream from Montreal on dining cars bound for the United States has been forbidden for some time. The same restriction pertains to vessels operating between Montreal and American ports. As the reported source of the epidemic appeared to be due entirely to milk, common carriers have not been forbidden to take on water supplies in that city.

New York City has placed an embargo on milk and cream coming from Montreal and adjacent territory. The same embargo if not effective now should be enforced by health officers of all upstate cities receiving any milk or cream from this source. Residents of this state visiting Montreal are advised to drink no milk or cream while in that city and, as an added precaution, should be immunized against typhoid fever.

The report of the Surgeon General states that in the period March-June 28 there were 4756 cases of typhoid fever and 453 deaths from that disease in the city of Montreal. For the 10 days ending June 28 the number of new cases averaged 10 per day, mostly contacts. Under the circumstances, no change will be made for the present in the embargo against milk and milk products coming from Montreal.

A chart attached to the Public Health Service report shows that the first high peak of

cases reported (160) was reached toward the end of March. The number of cases then fell sharply and remained at a fairly low level until the third week in May when two high peaks occurred three days apart (both 158) almost as great as the first.

In searching for the specific conditions which would permit such an epidemic to rage in a city of approximately 600,000 population, the following paragraphs in the report stand out as particularly significant.

### ADEQUACY OF LOCAL HEALTH SERVICE

"When the epidemic began, the city health department was operating on an annual budgetary basis of 40 cents per capita. The working force has since been augmented by the employment of four sanitary inspectors. Only one inspector is especially engaged in inspection of pasteurization plants, of which there are 41 or 42 in the city, and he is said to devote a considerable proportion of his time to other duties. The conditions generally found on the dairy farms indicate that the sanitary control of these farms has been and is yet far from adequate.

"Only eight health nurses are now engaged in communicable disease control work in Montreal. With over 3,000 typhoid cases or convalescents at homes in the city, and with the usual prevalence of other communicable disease, the inadequacy of such a small force of nurses is obvious.

"Our definite impression is that the city health officer of Montreal has honestly and sincerely recognized his responsibilities during the epidemic and has done his best to render efficient service under most difficult and trying circumstances. It is evident that he should be given ample authority and adequate efficient personnel at once to cope effectively with the present typhoid situation and with other serious preventable disease situations which are likely under existing conditions to develop in Montreal in the future. Such provision is of critical importance to all people of the city and would be to the business interests of all the citizens and especially of those who may profit from tourist traffic. Since the epidemic began the city health forces have been augmented by the temporary detail of two sanitary engineers and one sanitary inspector from the Provincial health department. This Provincial force took charge of the milk plant and the creamery of the Montreal Dairy Co., Ltd., on May 21, and apparently has managed them since in a highly efficient manner."

## THE CENTENARY OF "BRIGHT'S DISEASE"

In 1827 there appeared a two volume publication entitled "Reports of Medical Cases selected with a view of illustrating the symptoms and cure of diseases by a reference to morbid anatomy" It was by Richard Bright, then in the thirty-eighth year of his age, and was a record of cases treated by him during his six years of medical service at Guy's Hospital, London This publication contained the first clear recognition of the entity of common diseases of the kidneys His description of nephritis was so clear and complete that the sickness has ever since been popularly known as Bright's disease

The New York Academy of Medicine is recognizing the centenary of the publication of the "Reports of Medical Cases" by an exhibit of the books of the author and of articles relating to his life Among the exhibits is the *London Lancet* of October 10, 1925, which on page 769 contains a concise description of the life of Dr Bright and his investigations into the nature of nephritis, by Sir William Hale-White, M D, Consulting Physician to Guy's Hospital, in which Dr Bright did his work The occasion for the article was that of the first patient, John King, whose case was reported in Dr Bright's book and who was admitted into Guy's Hospital on October 12, 1825 Dr Hale-White says

"On October 12th, 1825, there was admitted into Guy's Hospital, under the care of Dr Bright, one John King, an intemperate sailor, suffering from general oedema, scanty urine, and pain in the loins He had haematuria but this passed away, and the urine, when clear, coagulated if heated, the pulse was hard The sectio cadaveris revealed acute pericarditis, oedema of the lungs, pleural effusion, a large heart, and ascites In Bright's own words —

'The kidneys were completely granulated throughout, externally the surface rough and uneven, internally all traces of natural organization nearly gone, except in the tubal parts This is a well-marked example of a granulated condition of the kidneys connected with the secretion of a coagulable urine'

"He inclines to the opinion that the 'disease of the kidney was the first established' He considers that neither the disease of the lungs, pleura, nor heart was the primary condition, nor was there any

disease of the liver to explain the ascites He points out that pain in the loins is a symptom of renal disease, and that 'the tendency to inflammatory affection in this man was a striking feature in his case and appears to me connected immediately with the condition of the kidneys'

This case was the first one of a group of twenty-three cases of nephritis which were published in the first 126 pages of Volume One Doctor Bright's description of kidney diseases was surprisingly modern, and his deductions regarding their primary origin in the kidneys is true to present day pathology He did for kidney diseases what his great French contemporary, Laennec, did for pulmonary diseases A second series of reports on kidney diseases appeared in Guy's Hospital Reports of 1836, in the form of two papers in which the symptoms, pathology and treatment are accurately described Regarding these papers Dr Hale-White says

"Assuredly this is one of the most astonishing series of papers in medical literature A disease, which presents symptoms of derangement of almost every organ in the body, is unerringly ascribed to the kidney We are shown how to diagnose it The description of its causes, its symptoms, its treatment, and its post-mortem appearances is so complete and accurate that after nearly a century no error has been detected and, if we except a few facts that have been gleaned by instruments which Bright did not possess, nothing of importance has been added"

Dr Richard Bright was born in Bristol, England on September 28, 1789 and died in 1858, aged 69 years He graduated in medicine from Edinburgh in 1812, and was made a licentiate of the Royal College of Physicians in 1816 He travelled extensively in his younger days He made a trip to Iceland and two through the continent of Europe, and published his observations in several books which he illustrated with his own drawings He became intensely devoted to the practice of medicine and to pathological research and spent six hours daily in Guy's Hospital He was recognized as one of the great medical leaders of his time, and in 1837 was made physician to Queen Victoria He was friendly to his colleagues and always gave them credit for their assistance

## CATTARAUGUS COUNTY MEDICAL SOCIETY

The Cattaraugus County Medical Society has adopted the plan of issuing bulletins to its members, thus allying itself with the Medical Societies of the Counties of New York, Erie, Kings, Queens, Suffolk and Bronx which already have bulletins

Bulletin Number One of the Cattaraugus County Medical Society is dated July 6, 1927, and is here printed in full—EDITORIAL NOTE.

### THE 1927 ANNUAL MEETING

The annual meeting for 1927 was held on May 17th, at Salamanca. The annual meeting has in the past been held in January but, due to the inclement weather then, it was felt that an annual meeting in a warmer month would be more convenient. The matter was discussed at the January meeting, a motion being introduced to amend the by-laws in this regard.

Members present at the annual meeting were Drs Happell, Hicks, Bennett, Johnston, Williams, Howard, J Ross Allen, Runals, Atkins, Reimann, Sheldon, Taggart, Greenleaf, Preston, Hillsman, Garen, Lawler, R. B. Morris.

Guests present were Archibald Dean, our District State Health Officer, Joseph A Wintermantel, M D, and Travis P Burroughs, M D (the latter two were elected to membership).

Business transacted. The matter of illegal practitioners, with especial consideration of the situation in Salamanca, was taken up. Following discussion the matter was referred to the Legislative Committee.

The by-laws were amended, making the time of the annual meeting the first Tuesday in May of each year.

The need for a committee on public relations was discussed. Upon motion the Committee on Public Health was enlarged by the addition of two members, and charged with the consideration of public relations. This committee is now the Committee on Public Health and Public Relations.

The following new members were elected.

Dr Joseph A Wintermantel, Allegany, Dr

Joseph Mountain, Olean, Dr Travis P Burroughs, West Valley.

A brief talk was given by Dr Dean, regarding post-graduate courses.

Dr C A. Lawler was appointed to act as a committee of one to arrange the details of post-graduate courses.

The Committee on Public Health gave a brief summary of its activities.

The secretary and treasurer reported for the year that there is a balance of \$196.50 in the treasury, the membership is now 54, and 26 members of the Society carry group insurance.

The following officers were re-elected: Dr J P Garen, Olean, President, Dr C A. Lawler, Salamanca, Vice-President, Dr R B Morris, Olean, Secretary-Treasurer.

The censors elected were W B Johnston, A. L. Runals, J A Taggart, M C Hawley, J Ross Allen.

Delegate to the State Society: M E Fisher, alternate, C M Walrath.

The new Legislative Committee is C M Walrath, Ellicottville, Chairman, M G Sheldon, Olean, J A Wintermantel, Allegany.

The new Committee on Public Health and Public Relations is L J Atkins, Olean, Chairman, P H Bourne, Salamanca, W E MacDuffie, Olean, Leo Reimann, Franklinville, F E Howard, Olean.

Dr M E Fisher read a paper reporting a case of undulant fever. There was a good amount of real discussion. (Dr Fisher's paper has been published in the *State Journal of Medicine*, issue of July 1.)

Increasing interest is being shown in the relations between the medical profession, official public health bodies, and the unofficial (lay) health organizations.

Be sure and read (1) The Relations of the Physician to Public Health—Hugh S Cumming, M D, (2) The Physician and the Public Health—Harlow Brooks, M D.

Both of these articles are in the *Journal American Medical Association*, July 2, 1927.

## DISTRICT BRANCH MEETINGS

Accounts of the preliminary conferences on the fall meeting of the District Branches were printed on page 736 of the July first issue of this JOURNAL. The most recent information is that the times and places for holding the meetings are as follows:

First District, October 20, in the Bronx.

Second District, some time in November, probably in Jamaica.

Third District, October 1, in Troy.

Fourth District, October 11-12, in Schenectady.

Fifth District, October 13, in Syracuse.

Sixth District, September 27, probably in Johnson City.

Seventh District, September 28, in Geneva.

Eighth District, October 6, in Glen Ayr.

# THE DAILY PRESS

## THE ROCKEFELLER FOUNDATION

Two great institutions for the promotion of scientific medicine are associated with the name of Rockefeller. There is the Rockefeller Institute for Medical Research, and there is the Rockefeller Foundation which makes practical application of the principles of medical knowledge to backward communities over the whole world. Concerning the Rockefeller Foundation the *New York Herald Tribune* of June 23 says editorially under the caption "St. George and the Dragon":

"One American institution spent nearly ten million dollars last year in promoting health throughout the world. Such great things have been done by it in other years that the magnitude and beneficence of its undertakings are not realized. The mere mention of the name 'Rockefeller Foundation' so promptly enlarges expectations as to prevent due appreciation of its service to humanity."

"The brief review of the year 1926 by Dr. Vin-

cent, President of the Rockefeller Foundation, with all its impersonality and absence of appealing illustrations of healing, is a document as full of the material of romance and chivalry as the *Idylls of the King*. St. George is fighting the dragon in a realistic and scientific way, whether the dragon be the hookworm in twenty-one different countries, yellow fever in two continents, or malaria in a dozen lands besides several of our own States. There is an even higher kind of service in providing for nurse training, helping medical schools to demonstrate plans for improvement in education, organizing rural health centres, supporting fellowships (889) for men and women from forty-eight different countries, and doing a score of other things to make the world a safer place to live in."

Physicians generally approve the editorial in both its spirit and its letter.

## PUBLIC SAFETY PERIOD

The three weeks beginning on July 18 have been set aside by Governor Smith as a Public Safety Period, with special reference to automobiles. The *New York Times*, of July 18, says editorially:

"The State Commissioner of Motor Vehicles has arranged with garage owners and service stations throughout the state to make free inspections of automobiles and their equipment at any time up to August 6."

But the auto is at fault less often than the man who drives it. Concerning this point, the *Times* says: "Yet it cannot be held that mechanical defects are the principal cause of the accident rate. Carelessness, drunkenness, speeding, reckless disregard of traffic regulations, take the heavier toll. But it is nevertheless true that a considerable proportion of motor-vehicle accidents is directly chargeable to faulty mechanism. Such accidents are particularly inexcusable, for they generally arise from sheer negligence. Nine out of ten of them could be prevented by regular inspection."

The *New York Herald Tribune*, of July 19, gives the following outline of the safety tests which garage men will apply to a car:

### TEST BRAKES

#### Requirements

- 2-Wheel Brakes—Car going 20 m p h must stop in 50 feet
- 4-Wheel Brakes—Car going 20 m p h must stop in 35 feet

Emergency Brakes—Car going 20 m p h must stop in 75 feet

Truck over 3 tons going 20 m p h must stop in 75 feet by foot brake

[Note—if you use a brake testing device, the equivalent of the above is required.]

### TEST HORN

#### Requirements

Press button and determine whether signal gives sufficient warning

### TEST LIGHTS

#### Requirements

- (a) New York State law requires 21 c p bulbs in headlights. Bulbs showing signs of blackening or a whitish discoloration inside of the glass are inefficient and should be discarded. They no longer give 21 c. p.
- (b) All bulbs which are burned out or missing must be replaced.
- (c) Lights must have proper lens, and reflectors must be bright.
- (d) All tail lamps must have a red lens.

### TEST STEERING MECHANISM

#### Requirements

Wearing parts must appear to be sufficiently strong so as not to indicate any possibility of breaking under ordinary conditions, thus causing an accident.

### TRUCK MIRRORS

#### Requirements

New York State law requires all trucks to be equipped with a mirror in such condition and so placed as to give rear visibility.

The time required for the inspection (no repairs or adjustments included) should be about ten minutes.

## ENFORCING THE MEDICAL PRACTICE ACT

The enforcement of the Medical Practice Act depends on at least five factors

- 1 The law
- 2 The prosecutor
- 3 The judge
- 4 The jury
- 5 The social status of the accused

The law regarding the practice of medicine is as clear and competent as any law can be

The leading prosecutor of violators of the law is the State Department of Education whose representatives are conscientiously eager to enforce the law and protect the people against ignorant healers

But now comes the weak part of the chain of procedure which leads to the conviction of quacks and the protection of the public. The final decision regarding the violators rests with judges and jurymen, many of whom are not familiar with the spirit and intent of the law, and know little of the scientific basis on which the Medical Practice Act is founded. It seems to be the psychology of judges and jurymen that their decision of conviction must be based on actual damage claimed by one who has been mistreated. It is not sufficient to show that the act of the defendant is illegal, and might result in injury or death, nor is the evidence of a hired detective usually sufficient, as is seen in the case of the chiropractor on Staten Island, where the judge decided that no law had been violated although the defendant had treated a woman detective for pay (see this JOURNAL, May 1, 1927, page 498). The Department of Education has found that two of the greatest elements that are lacking in the prosecution of quacks are, first, the unwillingness of the recipients of treatment to testify against the healers, and second, the attitude of the judges in holding that the practice of quackery constitutes merely a minor fraud.

However, the fifth element of the social status of the defendant enters into prosecutions against quacks. When a man goes in good society, maintains a showy office and dwelling house, and has a big bank account, the presumption of innocence is overwhelmingly in his favor when he is accused of violating a law. He is likely to be crowned as a martyr, and his prosecutors to be criticized for narrowness. An Indian is likely to be immune from prosecution for quackery, for the people generally believe in the potency of Indian medicines, and it was even written into the state law of the early '30s that any one could use native herbs in the treatment of diseases. The Department of Education has recently failed in securing an indictment

against an Indian healer in Oneida County, apparently because he was a native Indian. But the Department has had success against ignorant foreigners. The Rochester *Times-Union*, of June 26, says

"Emilio Michelotti, of 1384 Clifford Avenue, may have been a physician in Italy, but he is not a doctor in this country, it was proved yesterday afternoon in City Court. He was found guilty of practising without a license. Judge Kohlmetz fined him two hundred dollars. Deputy Attorney-General George Fleckenstein prosecuted."

An example of the successful prosecution of two colored quacks is recorded in the New York *Herald Tribune* of July 19. The newspaper gives an amusing description of two negroes who handled trunks by day and demons at night. They assured Mrs. S that the demons of rheumatism which tortured her would leave if they received a bribe. The patient produced the money, and went with the healers to the cemetery gate at night during a rain storm, where the healers bargained with the demons to let Mrs. S alone on payment of \$250. The money was thrown over the graveyard wall and the healers told Mrs. S that "if the ghosts did not throw it back, it was a sign that the bribe was sufficient and that her rheumatism would be cured within a day. They waited at the gate of the cemetery for a half hour, and when the ghosts did not return the box, Mrs. S trudged through rain to her home and went to bed, serenely confident that her troubles were over.

"However, something had gone wrong and when she awoke the next morning her rheumatism was so much worse that she could not get out of bed. A skeptical doctor told her she had had no business going out in the rain, and when she confided to him the story of the magical ceremony, he notified the police.

"Last night Professor Alsa Rajah and Professor Euba were arrested, charged with grand larceny. Professor Alsa Rajah told the police that he could not understand it, that he had actually put the money into the box and thrown it over the wall. He suggested that the ghosts must have double-crossed him. The police, however, do not believe that the double-crosser was a ghost."

One can readily imagine the contrast between the reception which the court gave to the negroes and that which it would give to an elegant chiropractor who demanded and got \$250 for promising to expel rheumatism from a suffering woman. But after all, convictions of any illegal healer will prepare the way for the conviction of all regardless of their status in the community.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

- BIRTH INJURIES OF THE CENTRAL NERVOUS SYSTEM**  
Part 1—Cerebral Birth Injuries By Frank R. Ford  
Part 2—Cord Birth Injuries By Bronson Crothers  
and Marian C. Putnam. Octavo of 164 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1927 Cloth, \$4 00 (Medicine Monographs, Volume XI)
- URINARY SURGERY** A Handbook for the General Practitioner By William Knox Irwin, M.D. 2nd Edition, revised and enlarged. 12mo of 271 pages. New York, William Wood and Company, 1927 Cloth, \$4 00
- PRACTICAL GASTROSCOPY** By Jean Rachet, M.D. Authorized translation by Fred F. Imianitoff, D.S.C. B.A. Octavo of 148 pages, illustrated. New York, William Wood and Company, 1927 Cloth, \$5 50
- PRINCIPLES OF CHEMISTRY** An Introductory Textbook of Inorganic, Organic and Physiological Chemistry for Nurses and Students of Home Economics and Applied Chemistry with Laboratory Experiments By Joseph H. Roe, Ph.D. 12mo of 378 pages, illustrated. St. Louis, The C. V. Mosby Company, 1927 Cloth, \$2 50
- TIGER TRAILS IN SOUTHERN ASIA.** By Richard L. Sutton, M.D. Octavo of 207 pages, with 115 illustrations. St. Louis, The C. V. Mosby Company, 1926 Cloth \$2.25
- MANAGEMENT OF THE SICK INFANT** By Langley Porter, B.S., M.D., and William E. Carter, M.D. 3rd Edition, revised. Octavo of 726 pages, illustrated. St. Louis, The C. V. Mosby Company, 1927 Cloth, \$8 50
- EXAMINATION OF CHILDREN BY CLINICAL AND LABORATORY METHODS** By Abraham Levinson, B.S., M.D. 2nd Edition. Octavo of 192 pages, with 85 illustrations. St. Louis, The C. V. Mosby Company, 1927 Cloth, \$3 50

- MANUAL OF BACTERIOLOGY** By Robert Muir, M.A., M.D., and the late James Ritchie, M.A., M.D. 8th Edition. Revised with the co-operation of Carl H. Browning, M.D., and Thomas J. Mackie, M.D. 12mo of 821 pages, illustrated. New York and London, Oxford University Press, 1927 Cloth, \$4.75 (Oxford Medical Publications)

# BOOK REVIEWS

**THE PSYCHO-PATHOLOGY OF TUBERCULOSIS** By D G MACLEOD MUNRO, M.D. 12mo of 92 pages London and New York, Oxford University Press [1926] Cloth, \$1.75 (Oxford Medical Publications)

This is an interesting group of essays on the Psychopathology of Pulmonary Tuberculosis, that is well worthy of perusal.

It can be read through in about one-half hour and while contributing nothing new or striking, is of value in reminding us that the personality of an individual suffering from Tuberculosis is subject to many alterations during the progress of the disease and requires as much consideration as does the disease itself.

FOSTER MURRAY

**MOTHER AND UNBORN CHILD** A Little Book of Information and Advice for the Prospective Mother By SAMUEL RAYNOR MEAKER. Octavo of 209 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$2.50

Another little book of information and advice for the prospective mother which answers very satisfactorily the questions which arise during the antenatal period, and covers the lying-in period as well. Simply and well told—not too much is said at any time. The title is different, and possibly poorly selected—but the book is otherwise well done.

C. A. G

**OUTLINES OF COMMON SKIN DISEASES INCLUDING ERUPTIVE FEVERS** By T CASPAR GILCHRIST, M.D. Octavo of 54 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$1.50

This book of pocket size is not meant to teach completely the characteristics of the common skin diseases which it includes but is intended as an outline by which the uninitiated in dermatology may be enabled to determine what cutaneous disease is causing a patient distress. The diseases, which are described in almost telegraphic style, are grouped under headings of both type of lesion, and regional distribution. Brief suggestions as to treatment are also included. A physician who, by the aid of this book, might determine his patient's ailment would, however, do well to refer to a larger text for a more complete description of the disease and its treatment than is possible or desirable in a book of this size. The few photographic reproductions in the text are really excellent.

E. ALMORE GAUVAIN

**MEDICAL CLINICS OF NORTH AMERICA**. Vol 10, No 1 July, 1926 (Philadelphia Number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

The issue is replete with interesting and worthwhile articles on common and rare conditions. The article by Dr Strecker is of interest and practical importance. Chronic Phosphorus poisoning is discussed, and cases presented. The latest treatment for polycythemia is discussed and a case presented.

**MEDICAL CLINICS OF NORTH AMERICA**. Vol 10, No 2 September, 1926 (Philadelphia Number) Published every other month by the W B Saunders Company Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

Riesman presents a new word into medical nomenclature in this issue "Myocardosis," which aims to cover those cases of chronic myocardial failure in which the signs of inflammation are lacking. This word will

probably become popular. Another cause of backache is presented, and will probably be taken up in other quarters, as that complaint is a source of much thought. Dr Stroud's article on Auricular Fibrillation contains the expression frequently, "The rhythm was definitely that of auricular fibrillation." Hitherto, the one characteristic feature of auricular fibrillation was the complete lack of rhythm. One or the other of these two words is poorly understood by the doctor. Articles on Jaundice, Tuberculosis, Hodgkin's Disease, and other subjects, make this issue of value.

**THE MEDICAL CLINICS OF NORTH AMERICA** Vol 10, No 3 November, 1926 (Mayo Clinic number) Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Paper, \$12.00 net, Cloth, \$16.00 net.

A multiplicity of subjects are discussed in this number from the case standpoint. Often inferences from the history do not seem to be justified by the final diagnosis, as is particularly illustrated in Case 3 and 4 by Dr Logan. It would be interesting to know why Dr Plummer gave his patient with myxedema thyroid extract in preference to thyroxin by mouth. The discussion by Dr Hench concerning the education of patients with arthritis is interesting, but when the doctor finds himself under other circumstances he will find that the system of education recommended by himself will not avail much either for the patient or for himself. One will find in this issue treatments for many of the troublesome entities of medical practice, but a fair knowledge of pathology will prove to anyone who reads the treatments that little is to be hoped from the treatments.

J ARTHUR BUCHANAN

**HELIO THERAPY** With Special Consideration of Surgical Tuberculosis By A ROLLIER, M.D. [Second Edition] Translated by G DE SWIETECHOWSKI, M.D. Octavo of 318 pages, illustrated. London and New York, Oxford University Press [1927] Cloth, \$6.25 (Oxford Medical Publications)

Dr Rollier has done much more than pioneer work in Heliotherapy, and in this, the second edition of his book, he presents a most interesting and instructive volume. There are many excellent and convincing photographs with which Dr Rollier substantiates his sometimes broad claims. Many readers will doubtless take exception to the criticism of surgical interference, but they must remember that this is based on years of observation of many cases. The tables of dosage are clear and easily followed, though of more interest than value to those of us who are limited to the use of artificial substitutes for sunlight. The book is very well printed and bound and is a credit to the author and to the translator. It is a valuable addition to any library and deserves careful study by the practitioner in any branch of medicine or surgery.

JEROME WEISS

**LESSONS ON MASSAGE** By MARGARET D PALMER. Revised and the Massage Section Rewritten by DOROTHY WOOD, M.R.C.S., L.R.C.P. Sixth Edition. Octavo of 320 pages, illustrated. New York, William Wood and Company, 1927 Cloth, \$4.00

This is the sixth edition of a book which first appeared in 1901, and which from the number of reprints seems to have enjoyed extensive popularity. The author, Mrs Palmer is the first person that held an appointment in the Massage Department in a London hospital which itself, was one of the first, if not the first, hospital in London to start massage.

The book was originally founded on lessons in massage given to pupils at the London hospital, and the later editions have been elaborated by material contributed by other workers in the same field, and taken from text books on anatomy, physiology and surgery. A very valuable part of the book is that devoted to massage measures in the treatment of fractures where it is especially important to prevent the formation of adhesions and to prevent the waste of muscles, and preserve the mobility in the joints of the limb. The illustrations are fairly numerous and explanatory, and the author has had the good sense to condense the text into the smallest space compatible with exactness, also to use a system of paragraphing which makes for easy reading.

WM HENRY DONNELLY

**THE TIRED CHILD** By MAX SEHAM, M.D., and GRETE SEHAM, Ph.D. With a foreword by ISAAC A. ABT, M.D. 12mo of 342 pages, illustrated. Philadelphia and London, J. B. Lippincott Company [c. 1926] Cloth, \$2.00

The authors cover a very important and somewhat neglected phase of child life. The relation between fatigue malnutrition and the influence of physical and mental rest on the undernourished child has long been known. However, this subject has not been, to the reviewer's knowledge, so completely covered and set forth as has been done here. The arrangement of the book is the division of the material into three parts. Part one deals with the elemental and fundamental principles of growth and development, as well as with the psychology and physiology of work and efficiency in childhood. Part two discusses the nature, the causes, the feelings, and the associated factors of fatigue. Part three lays emphasis upon the prevention and management of chronic fatigue as it falls within the influence of the parent, school, and teacher. An enormous amount of material has been gathered into the three hundred and forty-two pages of the book, which bespeaks the tirelessness of the investigators. The subject is well covered, the type is clear, the arrangement attractive, and a very complete bibliography is set forth at the end of each chapter. This book is one out of the ordinary, both in the subject covered and in the method of setting it forth, and as such, fills a very distinct want in the treatment of children.

WM HENRY DONNELLY

**APPLIED REFRACTION** By HOMER ERASTUS SMITH, M.D. Octavo of 131 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$2.75

The reviewer has a record of a blind spot mapped from a patient which showed a change which could have been interpreted as pathological. After the map was finished it was noted that the patient was pale, trembling and showed every evidence of terror. It developed that she was very much afraid that she was about to be hurt. In fact, some "kind friend" had told her that such an examination was very painful. She had just recovered from two serious operations, and had had much suffering. After the patient realized that there was no cause for apprehension, and was thoroughly at ease, a perfectly normal map was made. This is a very dramatic and tangible demonstration of the point which Dr. Homer Smith emphasizes so strongly in his very valuable little book on "Applied Refraction."

The reviewer, of course, does not agree in every detail with every point which the author brings out. If he did he would at least have been a twin brother to Dr. Smith. Nevertheless, one is impressed from start to finish with the orderly arrangement and thorough understanding of the factors as worked out.

Chapter II deals with the test chart. A single form is recommended.

Chapter III discusses the trial case very nicely and Chapter IV the frame. Expansion of these chapters would be very valuable.

One of the most difficult principles for the beginner to

grasp is that of the ophthalmometer and yet it is one of the simplest which he must understand. In Chapter V the author certainly succeeds in giving a clear and concise outline of its action and value. Chapter VI is devoted to the cross cylinder.

The next two chapters, VII and VIII, deal with physical and psychological factors of vision testing, while Chapter IX discusses certain phases of cycloplegia. Chapter X takes up points in the problem of "Refraction after operation for Cataract." This chapter particularly, contains many valuable remarks.

The chapter headings of the remainder of the book illustrate the manner of development which the author adopts. Each one is full of real meat for the hungry refractionist seeking real mental pabulum.

Chapter XI The Cycloplegic Correction

Chapter XII The Ametropes.

Chapter XIII The Myope.

Chapter XIV Astigmatia.

Chapter XV Refraction After Operation for Cataract.

Chapter XVI The Post Cycloplegic Correction.

Chapter XVII The Use of the Improved Test Chart and the Non-Cycloplegic Correction

Chapter XVIII The Anomalies of Accommodation and the Presbyopic Correction

Chapter XIX Refractive Changes Incident to Advancing Years

Chapter XX The Ophthalmic Lens

Chapter XXI The Bifocal Lens

Chapter XXII Muscular Imbalances and the Clinical Use of Prisms

Chapter XXIII The Mechanics of Visual Appliances

Chapter XXIV The Cosmetic Value of Glasses

Perhaps the author will revise the arrangement of his material and expand his work in what we hope will be many future editions, and perhaps he will include more of his splendid illustrations, for it is felt that such good material as he can put forth should be more than an appetizer in quantity. The most and the least experienced will profit by a perusal of this little book, and it would do the internist and neurologist good to go through it also that they may better understand what sort of a problem a refraction case presents.

JOHN N. EVANS

**A TEXT-BOOK OF CLINICAL NEUROLOGY** By ISRAEL S. WECHSLER, M.D. Octavo of 725 pages, with 127 illustrations. Philadelphia and London, W. B. Saunders Company, 1927. Cloth, \$7.00

We well might dare assert that the corner grocer or prosaic printer should be worthy the name of neurologist, if he peruse this excellent book. Of course we exaggerate a bit in our enthusiasm but Dr. Wechsler has indeed dealt with his subject from "Alpha to Omega" with such thoroughness that the most knowledge-thirsting, aspiring neurologist can here be sated. There is no complaint which can come to the attention of the practicing neurologist which is not portrayed in every detail, methods of examination, symptomatology, diagnoses and methods of treatments generously fill this valuable volume and render it highly commendable to the student of this vastly interesting and universally important subject.

M. L. A.

**NOUVEAU TRAITÉ DE MÉDECINE.** Publié sous la direction de G.-H. ROGER, F. WIDAL and P.-J. TEISSIER. Fascicule IX Affections du sang et des organes hématopoïétiques. Octavo of 802 pages, illustrated. Paris, Masson et Cie, 1927. Cloth, 80 Francs

This volume is the ninth of a reference series on medicine consisting of twenty-two volumes. It is concerned with the affections of the blood and of the blood making organs, it is produced under the direction of G. H. Roger, Fernand Vidal, and P. J. Teissier. The con-

tributors are Aubertin, Clerc, Kindberg, LeSourd, Mouguin, Pagniez, and Weil

The pathology of the red cell is discussed by Aubertin, who has written much on anemias. The pathology of the white cell forms an article of 244 pages by Clerc. Hemorrhagic diseases are described by Weil, LeSourd, and Pagniez. The pathology of the spleen is discussed in an article of some 230 pages by Aubertin and Kindberg, which is stated by the publishers to be the first treatise on splenic pathology from the medical viewpoint. The printing and illustrations are clearer than in most French publications, although the binding is rather poor. In extenuation, it must be said again, that most French books are published unbound, the binding being supplied by the purchaser to conform with the rest of the books in his library

W H D

**THE MODERN PRACTICE OF PEDIATRICS** By WILLIAM PALMER LUCAS, M.D. Octavo of 962 pages, illustrated. New York, The Macmillan Company, 1927. Cloth, \$8.50

The reviewer is impressed by the carrying out of the very first line of the Author's Preface, where he expresses his belief in the efforts to relate the study of the diseases of childhood to the positive aspects of health.

He realizes thoroughly and applies the fact that modern pediatrics more than any other line of ordinary practice is Health Conservation.

The directions in both general hygiene and diet and in the treatment of disease are very explicit and detailed. The illustrations are excellent and ample though not over abundant and the reviewer considers this an admirable addition to the works on Pediatrics

W D L

**A PRACTICAL TREATISE ON DISEASES OF THE SKIN** For the Use of Students and Practitioners. By OLIVER S. ORMSBY, M.D. 3rd Edition, thoroughly revised. Octavo of 1,262 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$11.00

This comprehensive book, in its third edition, has a number of excellent new illustrations, has been rewritten in part, bringing it as closely up to the minute as possible, particularly since about thirty new diseases have been incorporated within its pages. It is impossible to detail the review of a book of this character for one would have to read it to thoroughly appreciate that it is one of the really good texts on Dermatology.

The author's arrangement and his style make it an easy book to read and understand. The publishers have also done their work well except that it seems to the reviewer the paper is a little too highly glazed for comfortable night reading

E. ALMORE GAUVAIN

**HEALTH RECORD FOR CHILDREN** By J. THERON HUNTER, M.D. Octavo of 52 pages. Baltimore, The Williams and Wilkins Company, 1927

This volume is merely an accurate record of the health of the child, somewhat on the style of the baby books published by lay organizations, but in addition to the ordinary data contained in babies' record books, this takes up the appearance of the teeth, past history, illnesses of childhood, urine analysis, accidents, operations, specific diseases, and finally, protective measures with special reference to vaccination and toxin antitoxin injections against Diphtheria. There is no reading matter or text in the little volume, but as the author says, it makes it easy for the parent to maintain an accurate record of the health of the child, and also for the physician to treat each complaint of the patient more intelligently through a knowledge of what has happened in the previous life of the child. The book may be used by the physician also, as a record of his patients, being kept either at his office or in the homes of the patients

WM. HENRY DONNELLY

**THE ELEMENTS OF GENERAL ZOOLOGY** A Guide to the Study of Animal Biology, Correlating Function and Structure, with Notes on Practical Exercises. By WILLIAM J. DAKIN, D.Sc. Octavo of 496 pages, illustrated. London [and New York] Oxford University Press, 1927. Cloth, \$4.00

This text is a general guide to the study of animal biology. The subject matter presented is very extensive, and along with the general information furnished on each subject, instructions are included so that a reader may obtain and study material, which will familiarize the reader with the subject under discussion. The range is extended from the minute members of the animal kingdom to the largest. No one engaged in the practice of medicine can remain uninterested in any subject, which offers a possible medium of discovering causative factors of disease. Already small and large members of the animal kingdom have their pathogenic representatives, and there is little doubt that further study in the field will be without avail. Anyone desirous of making a general survey of the field will find this book of importance.

J. ARTHUR BUCHANAN

**PHYSICIANS OF THE MAYO CLINIC AND MAYO FOUNDATION** With Portraits. Octavo of 578 pages. Philadelphia and London, W. B. Saunders Company, 1927. Cloth, \$7.00

This volume represents the Surgeons, Fellows, and members of the Mayo Clinic, including the fellows prior to January 1st, 1926, who have spent one year or more at the Clinic.

A brief biography, a portrait, and a list of scientific contributions of each one is given. Although this book has no particular scientific interest, it should be of interest to all those who have been connected officially, or unofficially with the Mayo Clinic.

It will also serve as a reference book for those whose names are contained therein. HERBERT T. WIKLE.

**THE PRACTICAL MEDICINE SERIES** Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of CHARLES L. MIX, A.M., M.D. Series 1926. Chicago, The Year Book Publishers, 1926. General Medicine. Edited by GEORGE H. WEAVER, M.D., LAWRENCE BROWN, M.D., ROBERT B. PREBLE, A.M., M.D., RALPH C. BROWN, B.S., M.D. 12mo of 737 pages, illustrated. Cloth, \$3.00. Price of the series of eight volumes \$15.00

This volume contains a well-selected assortment of abstracts of representative articles published during the year 1926. It serves the useful purpose of keeping the physician informed of the advances in general medicine during the year.

FREDERIC DAMRAU

**THE NORMAL CHILD AND HOW TO KEEP IT NORMAL IN MIND AND MORALS** Suggestions for Parents, Teachers and Physicians, With a Consideration of the Influence of Psychoanalysis. By B. SACHS, M.D. Octavo of 111 pages. New York, Paul B. Hoeber, Inc., 1926. Cloth, \$1.50

This book is like the proverbial married man. It has a better half and a worse half. The opening sections are full of sound and commonsense statements, which should prove of great help to parents as a contrast to the highly fantastical literature on child culture so prevalent today. If Dr. Sachs had adhered to these tactics, his book would be deserving of unqualified endorsement.

But a loathing for candlesticks and phallic symbols and a personal resentment against the many biographies now written on the famous King Oedipus overcame the writer in the latter half of his book. Then Freud's "theories" were discussed in the heat of emotion rather than in the cold light of science. It would have been better not to discuss them at all.

FREDERIC DAMRAU

# OUR NEIGHBORS

## THE ARKANSAS MEDICAL SOCIETY ANNUAL MEETING

The annual meeting of the Arkansas Medical Society was held on May 11-13, 1927, in Little Rock, and its proceedings were reported in the *Journal of the Society* for July. The attendance was 433 out of a total membership of 1,229. The address of the President, Dr. J. M. Lemons, before the House of Delegates was a model of brevity and directness, and its latter half was as follows:

"The county societies all over the State are waking up to the fact that their respective societies depend on hearty co-operation and it is a fact, if we get anything out of our county societies we must put something in each meeting. Who make up these county societies? You and I. Our county societies are improving in their programs, but let's make them better.

"The question has been asked—is the *Journal of the Arkansas Medical Society* worthwhile? Should it be discontinued, or should it be continued? Some physicians say, 'well, I never look at the *Journal*.' That may be true. Some say it is too small and others will say the *American Medical Association Journal* is too large. So it goes. A State Medical Society without its own *Journal* is like a ship without a rudder."

President Lemons also was brief and concise in his annual address before the Society, as is shown by the following extracts:

"Our Student Loan Fund is a step in the right direction to make able physicians in our State, and great honor is due to the men who have charge of this fund to assist worthy young men in completing their medical educa-

tion. Let us help the committee all we can in handling the Student Loan Fund, to place it where it will do the greatest amount of good, and add to this fund from time to time as our finances permit.

"It has been suggested by some of our young graduates in medicine that our medical colleges should teach more about medical ethics. They say about all they hear while they are in college is how to avoid malpractice suits, but nothing is said about medical ethics. If the students had lectures on medical ethics when they go into general practice, they would not have to be arraigned before the County Medical Society for infractions. I am proud to say, however, that medical ethics is now being taught in our State Medical College by very able physicians, our President-Elect, Dr. H. Thibault, and the new dean, Dr. F. Vinsonhaler.

"The late ruling of the Nurses' Association is causing comment from a great many sources. The graduate nurse now only works twelve hours on a shift, let it be either day or night, and the Association refuses to let a nurse watch a convalescent patient through the day and night by having a cot placed in the sick room so that if the patient should need a little attention at night, she could be aroused and this attention given. The ruling of the Nurses' Association has caused quite a bit to be said about training practical nurses, that they may come in and do duty as has been done in the past in the convalescent stage of the patient. Read what Dr. H. A. Hare has to say in the *Illinois Medical Journal*, March, 1927. It is worth your time."

## FLOOD SANITATION

The July issue of the *New Orleans Medical and Surgical Journal*, the organ of the Louisiana State Medical Society contains the following description of Flood Sanitation written by Dr. W. R. Redden, National Medical Officer of the American Red Cross—EDITORIAL NOTE

"On April 28, 1927, the Red Cross National Medical Officer called the first flood health conference at Memphis to develop plans for the coordination of Red Cross medical and nursing services, the United States Public Health Service, the Army and Navy Medical Services, State Medical

Societies and the American Medical Association with the services of the seven State Health Departments in the flood area.

"The first important result of the conference was the definite recognition of the several State Health Officers as the officials in complete charge of all health and sanitation within their respective states and as the officials directly responsible for all such work. The second important result was the establishment of a central

(Continued on page 870, adv. xvi)

 "In SUMMER DIARRHEA we have a gastrointestinal disorder due to the toxins generated from the *bacteria in milk*."
 

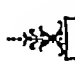

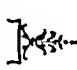

FISCHER, *Diseases of Infancy and Childhood*, Vol 1

# PREVENT SUMMER DIARRHEAS

*by*  
 Prescribing  *the*  
 Safe Milk

It is a well known fact that high atmospheric temperature has a definite bearing both on the child's digestive function and on its food intake. That the effect on the *milk* is the major evil is confirmed by the high morbidity and mortality rates during the summer months when bacteria are in their glory.

Pediatricists everywhere avoid the dangers of summer diarrheas by prescribing DRYCO, the safe milk in its most nutritious form. DRYCO keeps without ice, under all conditions of temperature and climate. The average bacteria count is invariably under 100 per C C, as compared to the 10,000 legally allowed to Certified milk.

*Samples and Clinical Data gladly*

  
*mailed to the Physician upon request*

# MAMMALA

## The Only Scientifically Modified Milk for Babies and Invalids

MAMMALA is pure fresh cow's milk of the best quality, modified for Babies, Children and People of All Ages by removing a part of its cream and by adding a suitable proportion of milk-sugar, and then dried rapidly by the scientific process of HATMAKER, which kills all disease germs that may be present and makes it safe and preservable. It is composed entirely of milk constituents and does not contain any starch, malt, cane-sugar, bicarbonate of soda or other foreign substance. It is a very nutritious balanced, complete food which is easily digested and very completely assimilated.

(Continued from page 868)

clearing house for all requests for personnel and materials and for all offers of service and materials. The conference voted unanimously to make the Red Cross Headquarters their clearing house, with Dr W R Redden, National Medical Officer, in charge."

Through these channels every State Health Officer has made known his needs, and not once in eight and one-half weeks has a single request been turned down.

The conference further recognized two definite phases in the emergency health and sanitation program, first, the refugee period during which thousands of people were suddenly driven out of their homes into camps and box cars, and second, or period of readjustment, measured from the time these people returned to their homes to the time when conditions of health and sanitation became comparable to those existing before the flood.

"Immediately plans were inaugurated to meet the needs of an effective program of health and sanitation. Already Surgeon General Cummings had assigned to the Red Cross Disaster Relief Headquarters as Liaison Officer one of the most outstanding Medical Officers of the Service, Senior Surgeon John McMullen, who took charge of the assignment of all personnel of the United States Public Health Service.

"The next step was to measure the number of health specialists and sanitarians and the amount of biologics there was available from State, County and Municipal Health Departments outside of the flood area. Within forty-eight hours, in response to telegrams sent to fourteen or fifteen State Health Departments we had listed seventy-five to eighty health officers, sanitarians, epidemiologists and chemists ready to give service with salaries paid by their respective states or counties, and expenses to be covered by the Red Cross."

Furthermore, it soon became evident that local county medical societies near or in the refugee camp communities had organized rotating visiting medical and dental services for the camp dispensaries and emergency hospitals. In addition to this, the health departments, assisted by the sanitary corps of the National Guards, established in each camp a sanitary service sufficient to guarantee safe water, safe milk, proper waste disposal, and clean food handling.

"The fact that during eight and one-half weeks there has not been a single outbreak of disease or a single epidemic of any kind in the camps, that even the ordinary ill-

nesses among the refugees have been far less than among a similar group under ordinary conditions, is the finest tribute to the splendid work of the doctors, sanitarians and nurses in these camps

"There is every indication that with the continuation of this work and the establishment of permanent local health measures the flooded areas may escape the ravages of the filth-borne diseases which invariably follow in the wake of floods"

The same issue of the Journal contains the following editorial description of the work of family doctors during the flood emergency —

*"The Flood and the Medical Profession* —Now that the flood is receding and there is time to think about what has been done during the past few weeks, we may safely say that the medical profession has on this occasion, as it has always done previously, met the situation. Whenever there is an emergency, it is always to the medical profession that the people go for help. In time of war or famine, pestilence or flood it is the old regulars who are appealed to for help. No matter how popular the various cults may be in time of peace, when there is any real trouble the regular medical profession is looked to and called upon.

"It is always the local physician who faces the real emergency. Often without adequate help and without sufficient supplies, it is he who must assuage the suffering and give first aid to the injured. It goes without saying that when the daily press states that the Red Cross is on the way and a train load of physicians and nurses is being sent, that the local doctors has already been on the job and has things well in hand by the time help—and much needed help it is true—reaches the 'front'.

"Recently Nicholas Murray Butler spoke of the doctor who cared mightily for every patient, who stopped at nothing, whose tenderness matched his skill, and whose devotion went parallel with his service. One more our hats are off to the home doctor."

## HOW TO CONDUCT A STAFF MEETING OF A HOSPITAL

The July issue of *California and Western Medicine*, the official organ of the Medical Associations of the states of California, Nevada and Utah, contains an editorial description on the plan of the staff meetings of an unnamed hospital. This plan is here reproduced for the benefit of New York physicians who are confronted with the problem of making the staff meetings practical and useful.—EDITOR'S NOTE.

## How Sanborn Metabolism Apparatus Will Help You

YOU can accurately diagnose many ordinarily perplexing cases with Sanborn Metabolism Apparatus. You can identify the important thyroid disorders, study and treat more intelligently many special cases in diagnosis, therapy and surgery.

Your patients will be gratified by this exceptional service.

### Metabolism Testing Aids Success

Why rely upon outside tests? You or your assistant can test metabolism quickly, easily and accurately in your own office with the

## SANBORN GRAFIC METABOLISM TESTER

\$165.

THE Sanborn Gratic is simple, compact, durable—scientifically precise. It automatically records every detail of the test on a chart ready for filing. Saves you the nuisance of laboriously taking down results.

You can make the test and get the basal metabolic rate in less than 15 minutes, without any complicated figuring. Any one can easily operate the Gratic. It's portable, and costs under 20 cents a test to run. Hundreds of eminent physicians—names on request—heartily endorse the Sanborn Gratic. It is well worth your while to learn more about it.

# PHILLIPS Milk of Magnesia

## THE IDEAL LAXATIVE-ANTACID

The name "PHILLIPS" identifies *G e n u i n e* Milk of Magnesia. It should be remembered because it symbolizes unvarying excellence and uniformity in quality.

Supplied in 4 oz., 12 oz., and 3 pt. Bottles

**THE CHAS. H. PHILLIPS  
CHEMICAL CO.**  
New York and London

# MAMMALA

## The Only Scientifically Modified Milk for Babies and Invalids

MAMMALA is pure fresh cow's milk of the best quality, modified for Babies, Children and People of All Ages by removing a part of its cream and by adding a suitable proportion of milk-sugar, and then dried rapidly by the scientific process of HATMAKER, which kills all disease germs that may be present and makes it safe and preservable. It is composed entirely of milk constituents and does not contain any starch, malt, cane-sugar, bicarbonate of soda or other foreign substance. It is a very nutritious balanced, complete food which is easily digested and very completely assimilated.

"In one of the hospitals with which the writer is connected a staff organization and meeting procedure has been worked out in the last several years that fulfills, we believe, the real purpose of a hospital staff organization, and this without infringing on the pre-existing or proper domains of other medical organizations.

"In this hospital of over three hundred beds there is not an overplus of staff meetings, there being only one such session per month. Provision is made for extra meetings, but these are rarely called.

"There are three to five presentations of history records of patients who have been under care at the institution. The history records selected by the program committee, after conference with the chart reading committee, are of that kind, wherein matters of diagnosis, treatment or pathology especially come into question, or which, for this, that, or the other reason should be of particular interest or value to the staff members.

"The presentation of the history record is kept as impersonal as possible. This impersonal element is very important. The clinical history, with case number, but not the patient's name mentioned, is compiled and read by one of the interns, who writes up the same from the history sheets. The name of the attending physician or surgeon is not known or mentioned, and the members of the staff do not know whose patient is under discussion unless the attending physician or surgeon chooses on his own account, before the discussion closes, to make a statement that acquaints the staff members with that fact. This presentation by an intern gives very good training to each house physician, means as a rule a presentation that is more pointed and more unbiased than if the attending man was making it, and the system whereby the name of the attending man is not known permits the later discussion to proceed freely, and without engendering misunderstandings.

"The program committee deputizes three members of the staff to open the discussion. Each of these, when he is notified that he is down for a discussion, is given a copy of the synopsis that has been previously prepared by the intern, and is told what particular phase of the general subject having to do with the disease under consideration, or any particular phase of the patient's clinical record, is to be discussed by him. Thus this plan provides that the discussion is opened by three staff

## THE SYSTEMIC TREATMENT OF SKIN DISEASES AN APPRAISAL OF SOME RECENT ADVANCES IN THIS FIELD, WITH A STUDY OF THEIR RATIONALE\*

By E WILLIAM ABRAMOWITZ, M D, NEW YORK, N Y

From the Department of Dermatology and Syphilology, New York Post Graduate Medical School and Hospital, New York.

THE use of external or of systemic treatment in various diseases of the skin, is dependent on the cause and nature of the pathological process in the skin on the one hand and the general condition of the patient on the other. The pomade for scabies and the potion for syphilis, to paraphrase Darier, expresses the relative value of each kind of therapy in cutaneous diseases of definite pathogenesis. Where the causes of certain dermatoses remain obscure, the valuation of local or systemic treatment is just as exact as the premises on which it is based.

Following the development of dermatology under Hebra and his pupils, progress in external therapy forged ahead of the systemic treatment, because attention was mainly concentrated on learning to "read the skin." Of late, blood chemistry studies together with the advances in immunotherapy, chemotherapy, endocrinotherapy and the role attributed to the vegetative nervous system in regulating cellular activity, influenced many dermatologists to employ measures more from the standpoint of the "internist," especially so in those dermatoses where the local therapy seemed to be inadequate.

Although such studies and the systemic treatment based on them, are still in the process of development, it may be of interest to evaluate such contributions to the therapy of skin diseases, together with the rationale on which they are founded. It will be necessary however, in order to avoid too lengthy a treatise, to limit it to just those systemic measures that are of special interest because of the results obtained, or an account of the hopes they have aroused.

Even with effective systemic treatment, it must be remembered that local therapy ought not to be neglected, if local symptoms require it or special circumstances demand it. Some contraindication may exist forbidding the use of an internal measure.

The subject matter is arranged under individual diseases of the skin and those considered as related. Syphilis is not discussed. A few dermatoses like acne, the seborrheoides and pruritus as well as some of the less common ones, are perforce omitted or mentioned only casually, unless some particular advance in their systemic treatment required it otherwise.

### TOXIC DERMATOSES

Except where they can be proven as due to foods (gastro-intestinal) or drugs, the etiology of the different types especially the erythema group, remains as a rule vague. No details are necessary as to restriction of diet and eliminative measures, when the toxic eruption is due to foods but a few words on the erratic behavior of idiosyncrasy in connection with drug eruptions, are appropriate, on account of its prophylactic value.

A drug may vary in its effects on the skin at different times in the same and different persons. Not only the erythema group but other types of eruptions, are also encountered. An early and sometimes a delayed rash occurs, or the eruption may fail to appear at certain times—the negative phase. The ill effects are sometimes known to absent themselves when the type of preparation is changed, as with iodine and arsenic.

In specific instances like mental and cutaneous bromism, Wile (1) induces an increased bromide excretion by intravenous saline infusions, in order to combat bromide intoxication. He thus reverses the phenomenon of the displacement of the tissue chlorides, following bromide medication. He uses normal and decinormal saline solution and gives it intravenously in amounts varying from 100 to 400 cc, at intervals of three or four days. After a few doses, a prompt improvement is noted in all skin lesions and other symptoms. The good effects of this treatment are confirmed by others and thus warrants its further employment in this obstinate dermatosis.

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 11, 1927.

**IODIZED TABLE SALT**

Iodine is necessary for the health of the human body, and its absence is a great factor in the cause of goitre. Although it is needed in only an extremely small amount, it is often almost entirely absent from man's ordinary food.

Iodine is deficient in foods derived from land plants and animals, but is abundant in those from the ocean. It also exists in natural salt, which contains a mixture of the minerals in the waters of ancient seas. But when the salt is "Purified," the iodine and other minerals are sometimes removed.

There are large areas in New York and other states in which goitre is prevalent because of the lack of iodine in the food and the water which the people ordinarily use. This form of goitre may be prevented by the use of common table salt to which a small quantity of iodine has been added. Some cities, Rochester for example, have added small amounts of iodine to their water supplies in order to prevent the common form of goitre. Anyone can accomplish the same result by habitual use of table salt containing a minute proportion of potassium iodide.

Such an iodized table salt may be bought from the Worcester Salt Company, 71-73 Murray Street, New York, whose advertisement appears on advertisement page xiv of this issue.—Adv

**HOW SANBORN METABOLISM APPARATUS WILL HELP YOU**

You can accurately diagnose many ordinary perplexing cases with this apparatus. Helps to identify the important thyroid disorders, to study and treat more intelligently many SPECIAL CASES in diagnosis, therapy and surgery.

**YOUR PATIENT WILL BE GRATIFIED BY THIS EXCEPTIONAL SERVICE.** Metabolism Testing aids success, why rely upon outside tests? **NEW DE LUXE EQUIPMENT—BUY THE BEST**

Our readers' attention is called to the advertisement of C. M. Sorensen Company on page xx of this JOURNAL. They will be pleased to send you, upon request, folder fully describing their equipment. Every unit is sold under the firm's full guarantee.—Adv

**COLOSTOMY APPLIANCES**

Within the last 10 years, the technique of colonic operations has been so wonderfully developed that thousands of patients have been saved. In order to assist those patients after the operation has been successfully performed, it was necessary to devise a Colostomy Pouch, which the patient can wear with comfort, in order to keep his body perfectly clean, and also supply him with an appliance which can be kept sterile.

**THE WILLIAM M. EISEN COMPANY**, after several years of experimental work, finally succeeded in perfecting a Colostomy Pouch, which has all the qualities and advantages required for that purpose.

**THE EISEN COLOSTOMY POUCH** is made with a pneumatic soft rubber cushion, inter-changeable receptacles, a very light non-rustable metal cup, and an elastic adjustable body belt which is detachable from the Colostomy Pouch. The cup and pouch which lies over the artificial rectum can be easily cleaned, and there is no possibility of any leakage between the pouch and the opening of the artificial rectum, when applied to the body.

This pouch is recommended by a great many leading Surgeons all over the country, and recognized as a most satisfactory appliance. See advertisement on this page.—Adv

**MAMMALA CORPORATION**

We are pleased to have Mammala return to our advertising columns. It was the original dry milk for Babies and Invalids and it has given the users great satisfaction for over twenty years.—See advertisement, page xvi.—Adv

**COLOSTOMY POUCHES**  
No. 3000

This apparatus for artificial Anus is the most sanitary and practical of its kind. The body plate and drain funnel are of white metal and a pneumatic ring between body of patient and plate serves to make the latter cling close to the body. Two rubber pouches of the necessary size are supplied in order that one may be thoroughly cleaned and disinfected while the other is in use.

**RECEPTACLE FOR NATURAL ANUS**

With Body Belt  
The only appliance made for the non-retention of stool. Will take care of the natural discharge in a cleanly and efficient manner. Made entirely of soft rubber assuring comfort to patients.

**SUPRA PUBIC DRAINAGE APPLIANCE**  
An apparatus devised for the purpose of receiving the Urine while drainage is taking place after a bladder operation.

identical. On account of its general utility, the term eczema will be used here, recognizing that the word creates in the mind of some dermatologists of note, an image quite distinct from a dermatitis.

According to Highman (6) eczema is neither an external nor an internal disease, but due to precipitating causes acting on a prepared skin. For practical purposes, however, the cure of eczema resolves itself into a diligent search for the external causes first and failing in this, for the internal causes. The rationale of such a procedure has its origin in the successful studies that uncovered many eczemas formerly considered of obscure internal origin, to be either a dermatomycosis, an occupational skin affection or a dermatitis of an anaphylactic nature. Knowles (7) from his studies arrives at the conclusion that in a large proportion of eczemas, some external cause will be found responsible and a cure result after the removal of the noxious substance. He further agrees with Hall, that numerous cases of infantile eczema are also exclusively of external origin.

Extreme adherence to externalism in eczema, that Hebra once sought, is not readvocate. It is recommended that priority be given to an examination for external causes and only exclude them after diligent and judicious investigation. A few significant case reports may serve to illustrate.

I presented before the Brooklyn Dermatological Society (8) an elderly lady, Mrs. L. B., who had a severe and generalized eczema simulating an exfoliating dermatitis. She had been under treatment on three different occasions at various hospitals. While under my supervision, the rash cleared up entirely under roentgen-ray therapy and arsenic injections, only to reappear as soon as the treatment was discontinued. Just about this time, it was discovered that she was using some kind of an insect powder in her apartment and when questioned as to any ill effects when employing it, was certain it made her sneeze and cough. Further investigation showed that the insecticide was pyrethrum powder. She used this quite liberally as her husband was in the business. Her skin was positive to pyrethrum and several relapses since, were traced to this powder still in various parts of her rooms. Her husband also discontinued handling this product.

A nurse was subject to repeated attacks of eczema until finally she had to be hospitalized for a severe and generalized outbreak. If she handled or was anywhere near lysol, she would promptly show effects on her skin. Another patient with an acute erythematous eczema of the face and neck, was isolated for a supposed attack of erysipelas. This lady was washing her face in a weak lysol solution, as someone told her it was "good for the skin."

A man, 54 years old, had a fissured eczema of

the tips of the fingers for about two years, and a tinea of the groin of unknown duration. The latter healed soon enough but the finger lesions remained about the same. I finally discovered that he was carrying some loose chewing tobacco in his pockets. As soon as he emptied them of the tobacco, the lesions responded to the same local treatment previously ineffective.

A 14 months old boy with an infantile eczema of the face and body, was treated by me ten years ago with local remedies. I saw him again about six months ago, with a weeping and pustular eruption on the chin, right hand and forearm. His physician informed me that one year ago, on account of the continual recurrences since an infant, he had the boy's skin tested and found it to be positive to silk. The present attack and others of a similar nature, were definitely noticed since then by the boy's mother, to follow contact with silk draperies, ties, mufflers, etc.

These are only a few of the more striking experiences encountered and just skim the surface of the numerous other external pathogenic factors that may act as irritants. Skin tests, and carefully planned questioning regarding details of occupation, as well as to contact with cosmetics, drugs, chemicals, dyes, plants, prints, shellac, hairs, feathers, silk, cotton and wool, soaps and other things thought to be harmless, are of considerable practical importance from a curative standpoint. According to Pollitzer, exogenous bacterial action is also culpable and should be eliminated by suitable local measures.

Eczematized ringworm is well recognized now and is usually amenable to local treatment. Psoriasis and other dermatoses when located in certain areas, closely simulate eczematized tinea and are no doubt often treated as such. Definite cases of tinea, resistant to local measures may be benefited if some form of systemic therapy, as discussed in endogenous eczema, is added to counteract any abnormal factors at play. If reinfection is to be avoided, all possible avenues of contact must be guarded against.

A consideration of the external causes of eczema is therefore essential for their proper investigation. Their detection and removal is an important part of the treatment, if a permanent cure is to be attained. Local measures in such cases are only palliative.

It is evident however, that even here a local and general predisposition exists, for not all coming in contact with external irritants, are susceptible. When such substances are of a protein nature, desensitization is sometimes tried especially where the external cause is difficult or impracticable to remove. Other non-protein substances may also be effective prophylactic and curative agents. At least that seems to be the case with the antigen advocated by Albert Strickler in ivy poisoning.

Aside from the predisposition necessary in ec-

The only contraindication to the use of this measure, is a co-existent nephritis in the patient

In bromide acne, an increase in the amount of table-salt added to the diet, may be sufficient to cause such lesions to disappear rapidly. It is possible that those patients with a low chloride component are more susceptible to bromides and the same thought applies to those with a low blood calcium content. For this last reason calcium therapy may be also of value in bromism.

McBride and Dennie (2) utilizing Ravaut's treatment of arsenical dermatoses with sodium thiosulphate, advocate this method not only in arsenic, but in mercury and lead poisonings as well. In the case of arsenical dermatoses, the beneficial effects of the sodium thiosulphate administration are based on various theories, but the increased elimination of the arsenic that ensues, *pari passu* with the local and general symptomatic improvement, points to its practical remedial value. Like adrenalin and atropine, the prior and subsequent use of thiosulphate is also capable of preventing, at times, the skin lesions and other symptoms due to the arsenicals. Preparations of calcium, glucose (alone or as a vehicle for the arsphenamines) and thiosinamine are being used with similar detoxifying effects. A test for susceptibility to drugs in general is available either by giving a minute dose by mouth, or if an arsenical, by the percutaneous route. The thiosulphate is also an efficient remedy in stomatitis due to mercury and bismuth, but of questionable benefit when used in mercurial poisoning or plumbism.

The sodium thiosulphate should be chemically pure and freshly prepared before use, as a 10 per cent solution in sterile distilled water. It is given intravenously in doses of 0.5 to 1.0 Gram, daily or every other day, for as many injections as are necessary. It is usually well tolerated, although frequent urination and bowel movements are occasionally complained of, especially when the drug is given by mouth. I have seen a toxic erythema develop after the oral administration of this drug and Frazier (3) reports two cases that developed a purpuric vesiculo-bullous dermatitis, subsequent to the intravenous use of thiosulphate.

Where the cause responsible for the toxic dermatosis is obscure, empiric treatment along the usual lines, is the only recourse.

### URTICARIAS

Aside from the urticarial wheals of factitious origin, urticaria and urticarial erythema sometimes appear after eating various foods, even though partaken of previously without any ill effects. On the other hand these foods and also substances of a foreign nature, may be the cause of regular relapses—anaphylaxis. If positive cutaneous tests are obtained, desensitization or removal of the cause proves valuable, especially where foreign proteins like silk, cotton, feathers, pollens, serums, etc., are found to be the disturb-

ing factors. Relapses of long standing may be finally conquered by these means, especially in those associated with asthma.

Duke (4) has shown that light, heat, cold and other physical agents are to be contended with, as they are capable of producing eruptions of the urticarial group. So can emotional distress, endocrine dysfunction, foci of infection and infestation or parasites, produce similar lesions. Treatment in these instances, directed to the proper channel, usually brings relief.

A trying situation exists where the incriminating cause, especially of the relapsing type of the urticaria, is difficult to detect. Pulay (5) in his studies, notes in such cases an increase of the uric acid content of the blood, often accompanied by a varying degree of hypercholesterinemia. The calcium component, he finds inconstant. Pulay considers that measures directed to reduce the uric acid in the blood are of prime importance in the treatment of urticaria of this type, and he therefore recommends a purin free diet, with the administration of cinchophen or its derivatives, and large doses of sodium bicarbonate. The sedative action of antipyrine and pantopon is also of benefit. In those showing a vagotonia, atropine is valuable. Adrenalin is only of temporary benefit. Where the calcium content is low, large doses of calcium carbonate are helpful.

Ichthyol internally, especially for the papulo-vesicular urticarias of infants and children (strophanthus), has some advocates, although the rationale of its action is disputed. The elimination of lactalbumin in the diet is also of help in such cases.

The chronic papular urticarias and prurigos, although histo-pathologically lesions of the exudative type, are from a clinical standpoint more related to the urticarial group. Pulay's blood chemistry findings in the prurigos are about the same as in other types of urticaria and he therefore advises therapy of a similar nature. Desensitization as outlined in urticaria is also of value here, especially in Besnier's prurigo.

The administration of yeasts, fermented milks and colonic irrigations, mostly on the basis of combating the intestinal flora, are recommended for urticarias and other dermatoses suspected to be due to autointoxication and intestinal putrefaction. In the prurigos, the results are disappointing. In chronic urticaria as well as other dermatoses like pruritus and eczema, some benefit is noted with these forms of treatment, although not often enough to establish them as therapeutic measures of importance. Whole-blood and autoserum injections have proven much more effective in such dermatoses.

### ECZEMA, DERMATITIS OR ECZEMATOUS DERMATITIS

Pusey and others are convinced that eczema, dermatitis etc., are histologically and clinically

this in itself is of considerable aid in restoring the skin to normal. The internal administration of sulphur and ichthyol preparations in adult and infantile eczemas, has some advocates, who base the beneficial action on the contraction of the vessels of the skin, caused by the sulphur excreted in the dermal tissues. The rationale however, of the external as well as the internal use of ichthyol preparations, is called into question, for it is shown to rest on very insecure grounds (15). When iodides are advocated in chronic eczema it is because of its action on the thyroid gland and the desired increase in metabolism that ensues.

The use of arsenic is of great benefit in many cases of chronic eczema otherwise resistant to other forms of treatment. This drug, frequently prescribed in this dermatosis and also in psoriasis, lichen planus, dermatitis herpetiformis, pemphigus, tuberculides, Kaposi's sarcoma, mycosis fungoides etc., is often administered in a haphazard manner without due regard to indications and the kind of arsenic advisable.

In syphilis, Vincent's disease and other spirochetal infections, a chemotherapeutic action in the true sense of Ehrlich, is desired and the arsphenamines are therefore indicated. Perhaps in lichen planus some such action also takes place, for the arsphenamines are capable of producing cures just as Enesol (Mercury salicylarsenate) and other forms of arsenic will do, excepting with more rapidity. In the tuberculides, the arsphenamines are favored because of their indirect stimulation of the defensive forces of the body and possibly, antibacterial action. In eczema and psoriasis where most of the pathology is located in the epidermis and corium, other forms of arsenic are just as available and in fact less dangerous. The administration of Fowler's solution, Donovan's solution and Asiatic pills, quite useful at times, is often poorly tolerated or abused by the patient and besides is not so adapted to the use of graded and larger dosages that is occasionally necessary. It is for these reasons that the subcutaneous or intramuscular use is found to be more applicable. As arsenic by injection is painful and in certain forms quite toxic, it is advisable to choose only those preparations in which such ill effects are missing, their efficiency remaining intact. Sodium arsenate, cacodylate and Solarson (a 1 per cent isotonic solution of ammonium heptenchlorarsonate), meet these requirements, the last being the least painful and without the garlic-like smell often noticed when the others are used.

The following formula of sodium arsenate is one in use where a rapidly increasing dosage of arsenic is contemplated

	gm	or c.c
Rx Sodii Arsenas	—

An injection is given every day, beginning with five drops and advancing by two or three drops daily until 20 to 30 drops is reached. This is maintained for about ten to twelve days, unless signs of intoxication appear before this. If not, the dose is slowly diminished to five drops and a rest period of three or four weeks ordered. While the dosage is at its peak, the patient may show some fever and albuminuria and feel quite shaken up. This so-called arsenical shock therapy is not without its beneficial effects, as is evidenced in the following case.

A young man with a severe generalized neurodermatitis that resisted for three years all kinds of treatment, including other arsenicals and the roentgen-ray, submitted to the discomfort of one course of rapidly increasing doses of sodium arsenate injections and was rewarded after three months by a complete cure. During this time he received only the mildest superficial roentgen-ray treatment and a local antipruritic lotion.

The dietary regime for skin diseases in general and eczemas in particular is based nowadays on the effect of diet on skin reactivity to light and other irritants. Various foods, for instance, poor in certain vitamins, produced among other things, pellagroid skin affections. It is known that certain metabolic products like sugar, lactic acid, urea and others are photodynamic.

Based on his rabbit feeding experiments, Luthlen recommends for an acute eczema a vegetable diet poor in oxalates\*. He also allows beef, well boiled, to remove part of the extractives, adding very little salt. The mineral salts of the vegetables, especially the calcium, with the alkaline and saline laxatives also ordered, reduce the irritability of the skin and so aid it to return to normal. I have made use of this diet in eczemas and think it is of benefit, but the lack of proper control of such measures and of the patients using them, makes it difficult to draw definite conclusions. The same applies to the purin and carbohydrate-free diets. It is also as difficult to appraise the results obtained in this disease from the use of fermented milks, yeasts and colonic irrigations.

In addition to the measures above cited some patients with chronic eczema of extensive distribution and marked lichenification require rest in bed and even psychotherapy. A change of surroundings or a different climate may also accomplish a cure. Whatever the reason for this beneficial action may be, the clinical results cannot be denied.

In the endogenous eczemas of infants and young children, the restriction of salt in food is recommended by Finkelstein, while others favor reducing the protein intake, or the fats, or the carbohydrates. The results are not easy to judge.

\* Tea, coffee spinach rhubarb sorrel and pepper have relatively large amounts of oxalic acid. Hutchinson, Robert. Food and Dietetics New York, William Wood & Co 1908 p 294

zema due directly to external irritants, precipitating causes of an internal nature, may be responsible for the inflammatory skin lesions. This is the so-called true or endogenous eczema.

Clinical observation indicates that various internal disturbances are often associated directly or indirectly with definite skin lesions. In the pruritus of icterus, the pigmentation of Addison's disease and the myxoedema of hypothyroidism, we have a few examples of a direct connection of internal disturbances with skin lesions. In diabetes, eczema and other skin lesions commonly appear and seem to require the help of an antidiabetic regime and often of insulin. Eczema and nephritis are likewise associated. The gouty and uric acid diathesis (arthritis) and the exudative diathesis (calcium deficiency?) similarly, direct the attention of the associated skin lesions, to faulty metabolism and inefficient excretion. Focal infection and endocrine disturbances are also said to be culpable factors.

Recently some animal experiments and studies of blood chemistry, further indicate some abnormalities associated with eczema and other dermatoses. Although the deductions from these experiments do not admit of final interpretation, the treatment based on them, seems to denote progress.

Luthlen (9) increased the reactivity of the skin of rabbits, by oat feeding and acid diets. The skin returned to normal in its response to irritants, by feeding the rabbits on calcium chloride and greens. Luthlen concluded from these and still other experiments of his, that together with a change in metabolism, there was also a change in the chemistry of the skin, which resulted in its altered reaction and thus explained the etiology of eczema. Klauder and Brown (10) confirm most of Luthlen's findings but do not agree with his conclusions. On the contrary they find that cutaneous sensitivity cannot be correlated alone with blood chemistry studies, particularly the calcium content of the blood, but the problem is still more complicated in nature. Pulay in his studies notes the presence of a hyperuricemia and often a cholesterinemia, hydrenia (weeping eczema) and hyperglycemia. Schamberg and Brown (11) report excessive uric acid values in this disease, also in pruritus and occasionally in certain other dermatoses. Ayers (12) pursuing the studies of the late Dr I. L. McGlasson on carbohydrate metabolism in eczemas and other dermatoses, discovered that one-fourth of the number with eczemas, show a low glucose tolerance test, with definite clinical improvement in many such cases following a reduction of the carbohydrate intake.

Michael (13) on the other hand, in testing 120 persons with uric acid, urea and creatinin, finds that they are not dermal irritants. From his study, the blood estimation of uric acid in eczema and kindred disorders is of doubtful

value. Michael and Nicholas further show that the intravenous injections of lithium urate solutions do not aggravate eczematous lesions. This evidence is of practical clinical importance as some eczemas are associated with gout and a hyperuricemia. In such cases a purin-free diet with cinchophen or its derivatives is suggested. While there may be some general benefit in doing this and as Schamberg reports, even beneficial effects on the skin lesions, final conclusions as to its efficacy await further studies.

Throne et al (14) recently report that in all cases of eczemas there is a marked increase in the sugar content in the blood stream as well as a high chloride content and that arsenic intoxication acquired mostly through industrial contact and occasionally through foods, medication etc, is the actual cause in a large percentage of patients applying for treatment for this skin disease. They treat such patients with a carbohydrate, nearly salt-free diet and in the arsenic cases with injections of sodium thiosulphate. Their results while promising, await further arsenic determinations in other skin diseases and in normal cases, before and after the use of thio sulphate, and without it.

The effects of calcium therapy in eczema and other exudative lesions, is explained by Luthlen, in that it reduces the irritability of the skin in various ways, either by the increased coagulability of the blood, diminished vascular permeability, or diminished irritability of the vegetative nervous system. According to Luthlen, the parenteral administration of colloidal substances can also reduce cutaneous irritability, by bringing about a change in the colloids in the body. Whole blood, autoserum, serums, vaccines, milk injections and blood letting, as well as sodium nucleinate and sodium silicate, are capable of causing such alterations and are hence worthy of trial in eczemas. Pulay attributes the action of colloidal therapy to cholesterol effects and to changes in the viscosity of the blood. Stejskal reasons that the injection of glucose is beneficial, because it influences the direction of the watery component in the dermal tissues (osmotherapy). There are other theories as to the action of these remedies especially the non-specific activation of the cells caused by foreign protein therapy. These measures are useful additions to our armamentarium in reducing skin irritability in eczema, even though agreement as to their rationale, is not fully established.

Antipyrin, Pyramidon, and Luminal have a favorable effect on eczema on account of their sedative action on the nervous system. Bromides have also a beneficial effect, when given by mouth, but since A. J. Lebedjew showed the intravenous method to be more effective in eczemas and other dermatoses its use has become still more popular partly because the itching is quite promptly relieved. There are other reasons advanced, but

results, even with the roentgen-ray treatment of the thymus, are difficult to value.

In chronic cases various preparations of arsenic are recommended. According to Jadassohn it is an efficient remedy, especially in the particularly obstinate variety located on the palms and soles. The sequelae that are apt to follow in some sooner than others, if taken over any length of time, must carefully be guarded against. On account of the severe and occasionally fatal reactions that may occur with the arsphenamines, their use in this disease, it seems to me, is unwarranted.

The approach to a rational therapy of psoriasis, from a systemic standpoint, is beset with many difficulties in the form of observations claimed as significant, by various observers. There are many instances of the disease in families, especially where gout or diabetes is prevalent. Various blood chemistry findings and endocrine disturbances are reported, also a parakeratotic diathesis, etc., but these findings, just as the absence of psoriasis in the full-blooded negro or its rarity in inhabitants of the tropics, are of little therapeutic help.

#### PARAPSORIASIS

This group of diseases under which different types are classified, is not so uncommon, judging from the number of cases presented at the various dermatological societies. Reported cures are, however, rare. Any measure thus far employed in this disease, rests mostly on empirical grounds and for that reason and also its unknown etiology, is difficult to appraise. Of the many systemic measures suggested, the hypodermic injection of pilocarpine to the limits of tolerance, is perhaps the best at hand, alone or combined with the ultra violet ray. Fred Wise some years ago cured one patient with the ultraviolet ray and recently informed me of another that he cured with pilocarpine injections. In one patient treated with pilocarpine rather persistently, I saw no improvement.

#### LUPUS ERYTHEMATOSUS

The results so far achieved with gold therapy, in this obstinate dermatosis, are so gratifying, that it promises to be the most important advance made in recent years, in the systemic treatment of skin diseases.

First employed many years ago in the treatment of systemic tuberculosis, Koch soon after his discovery of the tubercle bacillus, showed the inhibitory effect of gold on the organism *in vitro*. The development and trial of gold compounds continued until 1917, when Feldt introduced Krysolgan, a 4-amino-2-aurothiophenol carbonic acid. This and other gold compounds are being considerably used now in lupus erythematosus, on the assumption that the disease is of tuberculous origin.

Schamberg and Wright (22) after a prelimi-

nary trial with colloidal gold chloride, utilized for the first time in lupus erythematosus, the preparation championed by Mollgard for systemic tuberculosis. This gold compound originally prepared by Fordos and Gelis in 1845 for the toning of daguerreotypes, is known as Sanocrysin, a sodium aurothiosulphate. It seems to be quite adaptable for intravenous use and in proper dosage, comparatively free of reactions. An actual cure or marked improvement in the lesions is reported by Schamberg and Wright, in nearly one-half of the twenty-five patients with lupus erythematosus, treated with this preparation of gold.

There are no definite rules as to dosage, frequency or duration of treatment with the various gold compounds as yet, but Schamberg advises in using the gold thiosulphate, to start with 25 to 50 milligrams dissolved in 2 cc of sterile distilled water and increase the dose gradually every five to seven days until 100 milligrams are given. Although a safe compound to use, general and muco-cutaneous reactions may occur. A cautious dosage is advised in disseminated lupus erythematosus. Martenstein and others report good clinical reports with Krysolgan, Galewsky uses Triphal, while another compound called Aurophos also receives favorable mention. Several patients with lupus erythematosus of long standing have now been presented before the various dermatological societies in New York City, who have been treated with different gold compounds, and the results in most of the cases have been remarkably good.

Gold therapy is only occasionally beneficial in lupus vulgaris and other forms of skin tuberculosis and tuberculides. Dr. Schamberg kindly furnished me the sodium aurothiosulphate for trial in a particularly severe case of lupus vulgaris of the face and scalp. This patient, Ruth K., 12 years old, I last presented at the skin section of the New York Academy of Medicine, March 1st, 1927, as completely cured following 21 injections of the gold compound. Another patient, a young married woman with lupus erythematosus of the scalp, received 15 intravenous injections of the sodium aurothiosulphate, with marked improvement of the lesions. The treatment in this case had to be discontinued, however, on account of a pruritus and a lichenoid eruption that developed on her skin and buccal mucosa, probably due to the remedy. This toxic eruption disappeared in two weeks and two months later, the lesions on her scalp were completely healed.

It is still too early to say whether the results from this gold therapy in lupus erythematosus will be permanent in nature. It is possible that it may be of use also in preventing recurrences.

There have been some cases of lupus erythematosus reported, where the removal of a focus of infection, resulted in the healing of the lesions. This together with the occasional findings of a bacterial infection other than tuberculous, especially in the acute fatal cases of the disseminated

especially as the local remedies are occasionally beneficial in themselves. Where definite protein sensitization exists and asthma develops, eczema and other lesions may yield to desensitization.

In closing the topic of the treatment of eczemas, it will be seen that therapy is usually simple enough provided the external cause is determined and the predisposition altered. Failure to detect the external cause, places such eczemas in the true or endogenous group, although no positive assurance can be had that some possible external cause defying discovery, is still the exciting factor. Even an eczema associated with hyperglycemia, diabetes, nephritis, hyperuricemia or thyroid disturbance, must yield more than once in the same patient to the treatment of the systemic disorder, before it can be classed as definitely endogenous. For reasons that are patent, the term endogenous as applied to eczema is in many instances therefore misleading. The rationale of the treatment of eczema, including infantile eczema, may be interpreted from modern clinical and experimental evidence, as based on direct exciting causes usually of external origin, that require removal, less often and as difficult to demonstrate, of internal origin, that need correction, acting on a skin whose hypersensitiveness must also be remedied because its cellular activity, vascular tonus and regulating mechanism are no longer adjusted to maintain a normal response.

#### SCLERODERMA

Some progress has been made in the treatment of this disease. In the severe cases involving the extremities and also in Raynaud's disease, periarterial sympathectomy is reported as occasionally beneficial. In the ordinary cases, the prolonged use of thyroid extract, often helps, especially where an evident atrophy or degeneration of the thyroid gland exists.

Ayers (16) reported a few cases of scleroderma that seemed to be due to arsenical intoxication. I have seen two such instances, with improvement under sodium thiosulphate therapy. Greenbaum (17) demonstrated that thiosinamine (allyl sulphocarbamide), like sodium thiosulphate, acted as an efficient detoxifying agent in arsenical dermatoses, and it may be that the good results occasionally secured by injections of thiosinamine in scleroderma, is not alone due to its resolvent action on fibrous tissue but also to its detoxifying action in cases probably due to arsenic.

#### DERMATITIS HERPETIFORMIS

Duhring's disease is very recalcitrant to any kind of treatment. Injections of autoserum, autohemoserum, glucose and some form of arsenic, are in common use today, in addition to the local therapy. I have aborted two sharp relapses in a patient, with biweekly intravenous injections of 10 cc autoserum with an equal amount of Ekzebrol (a 10 per cent sterile solution of strontium bromide in normal saline).

This patient was subject to the disease for eight years and had received in the way of treatment almost everything recommended for this disease, even circumcision, but never obtained as quick relief as with the bromide and serum injections. The basis for this treatment was already discussed under eczema.

#### PEMPHIGUS

Although the etiology of this disease is still undecided, the different remedies suggested are mostly based on a possible infectious or neuropathic origin. Kartamischew (18) has called attention to a sodium chloride retention and eosinophilia. He especially noted this in early cases that start with mouth lesions, and attached both diagnostic and prognostic value to these findings.

Davis and Davis (19) reported cures in a small number of cases of pemphigus after the clinical trial of their intravenous iron cacodylate and subcutaneous coagulen injections. The late Dr Grover W. Wende, employing their methods, also reported favorable results. Unfortunately the reports from other parts of the country have not been so good. Sustained and heroic doses of arsenic (Solarson), have cured two cases of pemphigus vulgaris under the care of Dr. Fred Wise. Others have had promising results with intravenous injections of quinine and sodium bicarbonate solutions and various dyes and the subcutaneous injections of various proteins, vasoconstrictants and vaccines. As Wise (20) suggests, the effects of treatment are probably dependent on the type of pemphigus. The acute, septic, bullous type being invariably fatal, the others, subacute, showing remissions and relapses, with bullae, vegetations or foliaceous scaling. Although the latter may occasionally be benefited, they ultimately succumb to the devastating effects of the disease.

#### ROSACEA

The internal administration of dilute hydrochloric acid, has in my hands been of great help in alleviation and prevention of relapses, of this disease, in addition, of course, to the other recognized procedures. This internal therapy seems to correct the hypo or achlorhydria that Ryle and Barber (21) finds to be quite common in such patients.

#### PSORIASIS

Although nothing definite has been accomplished in the prevention of relapses or hastening the disappearance of the lesions, no reason exists for the impression now prevalent among psoriasis patients, that they must go around decorated with the silvery scales. Each new outbreak should receive attention to prevent chronicity. Autoserum when combined with local treatment seems to be efficacious in my hands. Thyroid and thymus extract, entero-bacterins and various drugs are from time to time hailed with enthusiasm, but the

produced is only slight, to repeat it every two or three days with stronger dilutions of 1-50, 1-30, and finally 1-10. Eight to ten treatments are required, and during this time some form of mild local application may be used. Scholtz thinks this method just as effective as when given subcutaneously, even though the severe local reactions are absent.

Superficial types of ringworm infections and favus are not amenable to vaccines, although such measures have been tried. In tinea capitis and favus, the treatment with the roentgen-ray has not been surpassed.

#### OTHER PARASITIC DISEASES

In the impetigos, the local remedies are usually successful, while in furunculosis, relapsing folliculitis and sycosis vulgaris, resort to some stimulation therapy is often desirable in the form of a staphylococcus or mixed vaccine, milk or turpentine injections. There is a tendency to use the vaccines intracutaneously just as is done with milk, and a suggestion made in sycosis vulgaris, to inject at the site of the lesions, in order to increase the local immunity of the skin. The intravenous use of mercurochrome-220 soluble is advocated by Hugh H. Young in aggravated infections of the skin in general, as well as abscesses, cellulitis etc., and in various dermatoses. It is evidently a drug of marked germicidal value and worthy of trial particularly in streptococcal, staphylococcal and other bacterial inflammations of the skin of a severe nature. In doses up to 5 milligrams per kilogram of body weight, the intravenous use of this drug, is according to Young, practically unaccompanied by any danger.

In Sporotrichosis, potassium iodide in large doses has proven quite effective. In Actinomycosis or Blastomycosis, the use of the iodides is only of temporary benefit.

Progress in the treatment of Leprosy has been made with the use of the ethyl esters of chaulmoogra oil. A considerable part of the benefit derived from these oils and their esters is considered by Sir Leonard Rogers as due to the local reaction produced and to a specific effect exerted to a certain degree directly on the bacilli. It is impossible to prophesy in a disease that may remain latent for many years and then light up into an acute form. Yet many cases of leprosy are reported as free of all signs, after the prolonged use of the esters and it is hoped they will remain so. The results from the use of other remedies in this disease offer very little as yet to compare with chaulmoogra oil derivatives.

In Granuloma Inguinale, the intravenous use of tartar emetic is of decided chemo-therapeutic value. It is advisable not to sterilize the solutions by heating as a decomposition of the drug may occur. A Chamberland filter will avoid this. A Randall finds antimony thioglycollamide and

sodium thioglycollate, first used experimentally by Rowntree and Abel, in trypanosomic infections in animals, very efficient in granuloma inguinale and in higher doses less toxic. I have tried these compounds and also find them to be much better tolerated than the plain tartar emetic. Goldzieher and Peck think the bacillus venereogranulomatosis, the causative organism of granuloma inguinale and use a vaccine of this organism in conjunction with antimony. Their results seem promising, but further confirmation is necessary. In some phagedenic ulcerations of the genitals, antimony compounds are also of service.

Dermatoses like plane warts and molluscum contagiosum, are evidently of parasitic origin, possibly of the nature of a filterable virus. Some form of arsenic may produce a cure occasionally in either of them. I have seen fair-sized lesions of molluscum, fall off after one injection of arsphenamine administered for some other purpose. Richard L. Sutton on account of a similar experience with sulpharsphenamine in flat warts, recommends its further trial in such cases. In flat warts, especially in youngsters, the mercury protoiodide pills first suggested by Chas. J. White, will be found more simple and efficacious.

#### SUMMARY AND CONCLUSIONS

In the recent voluminous contributions to dermatotherapy, the systemic treatment receives more than the customary attention, owing to the advances in blood chemistry studies, immunology, chemo-therapeutics, endocrinology and studies of the vegetative nervous system.

Some of the systemic measures are effective, others less so. Even when effective, the local measures should not be neglected, if indicated.

Advances in knowledge of drug idiosyncrasy, has been of definite prophylactic value, and in specific instances like arsenic and bromide intoxication, also of curative value. Little progress has been made in the systemic therapy of the other toxic dermatoses.

The association of urticarial lesions with agents of a physical, chemical, parasitic, endocrine and psychic nature, is at first glance confusing, but the studies in connection with asthma, hay-fever, serum sickness, etc., point to the correlation of these different causes of urticaria and serve as a basis of some form of rational therapy. To a certain extent, this also applies to the prurigos.

The rationale of the treatment of eczema, including infantile eczema, is based on direct exciting causes, usually of external origin, that require removal, less often and as difficult to demonstrate, of internal origin, that need correction, acting on a skin whose hypersensitiveness must also be remedied because its cellular activity, vascular tonus and regulating mechanism are no longer adjusted to maintain a normal response.

type, speaks in favor of other causes besides tuberculosis, as responsible for this skin disease.

One other point is worthy of mention, and that is the frequency of external irritation, especially sunburn, given as a causative factor in lupus erythematosus, as well as the photosensitiveness of the skin, after the disease is developed. Pulay on the observation of one case, that showed a uric acid retention, suggests a purin-free diet and the administration of cinchophen to reduce skin photosensitiveness. Michael in his studies could not find any demonstrable photosensitizing effects in urea, uric acid or creatinine, in patients with various skin diseases or normal skin. He did not test the skin of any patient with lupus erythematosus. Great caution should be exercised in applying physical measures in which any form of light enters, in the treatment of this disease. Mild exposures and not over too large an area, with adequate protection of the uninvolved skin is necessary to prevent a possible dissemination of the lesions.

The tuberculin treatment of this disease, even when presumptive evidence exists of its tuberculous origin, is far from satisfactory. The tuberculin treatment in general will be discussed under tuberculosis.

#### TUBERCULOSIS AND TUBERCULIDES

The rationale of the systemic treatment of parasitic skin diseases in general, whether local or circulatory in origin, is based on specific immunity, non-specific stimulation of the general defense mechanism and chemotherapy.

In the use of tuberculin, immunotherapy plays a rôle of no minor importance, but as two apparently similar cases of skin tuberculosis will respond to tuberculin treatment in a totally different manner, other factors must also be considered.

The choice of the different methods of using tuberculin seems to depend on whether a specific immunity is sought, a stimulation of the general defense mechanism desired or perhaps on both factors combined. As an example, the method advocated by MacKee (23) is probably based on specific immunity. He uses the Bacillus Emulsion and begins with a very small dose,  $\frac{1}{2}$  cc of 1-50,000 dilution. The dose is increased by geometrical progression every five to seven days, at the rate of 25 per cent of the previous dose, at each injection. All reactions are avoided and treatment continued until a cure results.

Another method probably based on both factors is to use somewhat larger doses, i.e., 0.25 milligrams of old tuberculin and increase the dose every five to seven days, by 0.25 milligrams or more until two or three milligrams are reached. The increase in dosage is carried out in such a way that you obtain a definite local reaction after each injection, waiting for the old reaction to subside. The appearance of a strong general reaction without any local reaction, is a sign that the treatment must be given up.

MacKee cured with his method all of his eight cases of Bazin's disease in six to ten months time. One patient had a slight relapse. Lupus erythematosus and papulo-necrotic tuberculide failed to respond. The non-ulcerating type of lupus vulgaris showed some cures in contradistinction to the ulcerating types, that did not respond at all. The results in other forms of tuberculosis were mostly unsatisfactory.

Scholtz (24) uses old tuberculin and thinks the results are better where local reactions are produced. He prefers this treatment in Bazin's disease and lichen scrofulosorum and also in serpiginous lupus. In the other types of lupus vulgaris, scrofuloderma and tuberculosis verrucosa cutis, he uses the tuberculin as an adjuvant to other forms of treatment.

There are various kinds of tuberculin and still other methods of employing them, such as intracutaneous injections of mild and weak dilutions and Pondorf's scarification procedure with undiluted tuberculin, mostly based on the local development of skin immunity. Scholtz thinks the intracutaneous method more often beneficial, especially if combined with small doses of arsphenamine or glucose injection. Stokes (25) is favorably impressed with the use of the arsphenamines alone in the tuberculides, especially when the treatment is persistent and systematic and the cases properly selected. The action of the drug in this instance is probably due to indirect stimulation of the defense forces of the body.

In tuberculosis of the skin and more so in the tuberculides, occasional spontaneous remissions, makes it difficult to judge the value of a remedy unless healing of the lesions takes place in a shorter period under treatment than without it. Unfortunately with tuberculin therapy, it may be a matter of many months, before a cure can be accomplished and this may be also the case with the arsphenamines in tuberculides. Until something better is discovered, the patient is entitled to these measures, provided they do not interfere with the general health and are accompanied with other aids that are known to arrest systemic tuberculosis.

#### DERMATOMYCOSES

Scholtz thinks that the favorable effects produced by Trichophyton in tinea profunda, should be considered on the basis of immunotherapy. He reasons that while the injections of milk and turpentine also act favorably in this disease, they are also beneficial in other dermatoses, while Trichophyton is only so in trichophytia profunda. Martin F. Engman recently demonstrated that intravenous injections of typhoid bacilli suspensions will cure large-spored ringworm infections of the beard, and of the scalp. Scholtz' reasoning may apply to this method also. The treatment by Trichophyton consists in making 4 to 8 intracutaneous wheals of a 1-100 dilution of Trichophyton, on the forearm, and if the reaction

## INDICATION AND CONTRA-INDICATIONS FOR CESAREAN SECTION\*

By WILLIAM T GETMAN, M.D., BUFFALO, N Y

THE large increase in the number of Cesarean sections being done during the past five years throughout the country very properly brings before us the consideration as to whether the frequency of this operation is justified or not, and a statement of its indications and contra-indications

The ease and safety with which it can be performed, if the ordinary rules of modern surgery are followed, has tended to make it popular both among the profession and among women. The short time it takes for its performance, the absence of shock, of lacerations and injuries to the mother's soft parts, no injuries to the baby's head, and no birth palsies, make a decided appeal to the physician, while the relief from the suffering of a long or dangerous labor appeals even more strongly to the mother. If this could be done always with perfect safety to the mother and with a certainty of no bad effects in subsequent labors, we would indeed have arrived at an obstetrical millennium

We all realize, however, that we have not as yet arrived at such a millennium, and the reason is that there is still a definite morbidity and mortality to any laparotomy, no matter how skillful the operator or how favorable the surroundings

With the small scar high up on the abdomen

there is now no danger of postoperative hernia, but we cannot observe the healing of the uterine incision or judge its reliability when put to the strain of the next labor. We still see deaths from peritonitis in cases that supposedly have not been infected

Therefore, in considering the mode of delivery of our prospective mothers, we must consider not only the immediate morbidity and mortality, small as it is, but the possibility of rupture of the uterine scar under strain. Bearing these dangers in mind, there is a small but definite group of cases which can be delivered more safely by abdominal section than by the natural passage, and in my opinion, it is only by adhering closely to the more or less definite indications rather than operating on all possible cases, that we can keep this valuable operation from falling into disrepute

I will not go into the history of Cesarean section except to recall to you the statement made in the early eighties that "the mortality of Cesarean section when performed by American bulls was lower than that by American surgeons" and to point out that its safety has increased with the application of asepsis and the small high modern incision, as well as the delivery of the child without bringing the uterus outside of the abdominal cavity

In looking over the recent literature on the subject, I find a very large number of conditions

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls N Y May 11 1927

Colloidtherapy, osmotherapy, protein therapy, endocrinotherapy, calcium and bromide therapy, arsenic therapy, desensitizing and detoxifying agents, alkalinization and psychotherapy, are all directed to reduce this cutaneous irritability

A few cases of scleroderma are shown to be associated with arsenic in the blood and some cures have been obtained with sodium thiosulphate, an arsenic detoxifying agent. Perhaps the action of thiosinamine in this disease may be explained similarly

Bromides intravenously are very effective in dermatoses with marked pruritus, and may be of value in Dühring's disease when combined with autoserum, in aborting relapses

In Pemphigus, arsenic is still the remedy of choice, although the iron cacodylate and coagulen injections of Davis and Davis, have also been successful. If relapses occur the patients are usually doomed

The treatment of Rosacea is more efficacious if dilute hydrochloric acid is administered for the accompanying hypo or achlorhydria

Each new outbreak of psoriasis should be treated, to prevent chronicity. Some suitable arsenic preparation, not the arsphenamines, combined with autoserum and local therapy, offers results equal to any

Arsenical preparations, if carefully chosen and used with discrimination, are also beneficial in other dermatoses like lichen planus, Kaposi's sarcoma, mycosis fungoides, etc

In Parapsoriasis, pilocarpine by hypodermic injection is worthy of further trial. A few cures are reported

Honorable mention goes to gold therapy in lupus erythematosus, for the results thus far obtained, are beyond anything hitherto observed with any other form of treatment. The removal of foci of infection and protection against the effects of skin photosensitization are also a part of the management of some cases

Cures are reported with tuberculin in Bazin's disease, Lichen Scrofulosorum and the non-ulcerating and serpiginous types of Lupus Vulgaris. Arsphenamine has its beneficial effects in tuberculides, in selected cases and can be used alone or in conjunction with tuberculin. Gold therapy is also occasionally of curative value in some tuberculous lesions

Trichophytin vaccine is probably a specific treatment for tinea profunda, although intravenous injections of typhoid bacilli suspension, intramuscular injections of milk or turpentine, as well as definite local measures, may in some instances produce quite as efficient results

In Furunculosis, relapsing Folliculitis and Sycosis Vulgaris, the local measures are usually supplemented by vaccines and milk injections, preferably given percutaneously and in sycosis,

recommended at the site of the lesion, to increase the local immunity. In severe skin infections, mercurochrome-220 soluble in proper dosage and intravenously, is worthy of trial

Protoiodide of mercury in flat warts is successful in most instances, in causing these lesions to disappear, if it is not, sulpharsphenamine may be tried by injection. In molluscum contagiosum some arsenical may also be tried, when the lesions are numerous

Sporotrichosis is amenable to cure with large doses of potassium iodide by mouth. Actinomycosis and Blastomycosis much less so. In Leprosy, the ethyl esters of chaulmoogra oil, offer a definite advance in the treatment of this disease and it is hoped that further studies will eradicate this scourge. In Granuloma Inguinale and some Phagedenic Ulcerations of the Genitals, tartar emetic and other antimony compounds have been of definite benefit

The treatment of skin diseases is being placed more and more on rational scientific procedures. Dermatologists of wide clinical experience, who developed the local treatment of skin diseases to its present high peak of usefulness have turned to the methods of the internists, and in many instances have directed or performed many of the experiments that are responsible for whatever effectiveness the systemic measures accomplish in various dermatoses. The proper conception of the various problems involved, their proper solution and the effects of a remedy in skin diseases, is best interpreted by such experienced clinicians

Contrary to the opinion prevalent in some quarters, dermatology in its present aspect, is a specialty requiring diverse talents and years of effort, before sufficient skill is developed in mastering it. It is natural to look for further progress from those adept in this field, and considering the contributions thus far made, the outlook is hopeful

the tubera ischi measures less than 8 cm the anterior and posterior sagittal should be estimated. If the posterior sagittal falls short it is better to do a Cesarean than to subject the baby to the danger of cerebral hemorrhage from a difficult forceps extraction. As has been aptly pointed out, "It is sometimes easy to get a head into a pelvis but difficult to get it out."

**Habitual Fetal Death in Labor**—We should do our best in these cases to determine the cause of the previous deaths, by Wassermann reaction, careful exploration of the pelvic cavity, etc.

If we are unable to ascertain the cause and are, therefore, unable to correct it, I feel that these women are entitled to Cesarean section to obtain a living child.

**Tumors Obstructing Birth Canal**—Tumors obstructing the birth canal form a more or less definite indication for section. These may be uterine fibroids, or the various solid or semisolid ovarian tumors, but as they often become gangrenous from labor pressure or torsion of the pedicle, it is safer for the mother not to subject her to the risk of labor. In this instance, the low or median incision should be used and the tumor removed, if pedunculated, after the uterus is closed. Nonpedunculated uterine fibroids may be removed before pregnancy or fairly early in it, but at term they are not a cause for Cesarean unless obstructing the canal and could be removed between pregnancies if thought best. A pedunculated tumor may be a cause for section for fear of torsion, whether obstructing the canal or not.

**Prolapsed Cord**—This complication in a multipara should practically never be cause for section. In nearly every case the cervix could be dilated, manually, rapidly enough to permit the delivery of a living child by version. In a primipara with rigid cervix it may be justifiable, but here it is entirely in the interest of the child, and the case should be stated clearly to the parents, leaving the decision with them.

**Placenta Previa**—To make a statement positively that placenta previa should or should not be treated by Cesarean section is irrational. There are so many factors differing in different cases that the treatment of the one in hand would have to be decided on what presented in that particular instance.

No one would agree that all placenta previa should be treated by section, and certainly no one should say that no placenta previas should be so treated. The ordinary classification of placenta previa is that of marginal, or only a slight encroachment on the cervix. Partial, or the os partly covered by placental tissue. Complete, the os completely covered. Central, the os not only completely covered, but near the center of the placenta.

The marginal or partial varieties usually cause

us but little anxiety or trouble, and often as simple an expedient as rupturing as membranes and allowing the head to come down on the detached area will arrest the bleeding. If this does not accomplish it, a Voorhees hydrostatic bag will almost certainly do the work, and at the same time give us the much desired dilatation for delivery.

A complete placenta previa is a much more serious affair and often taxes the skill of the accoucher to the utmost.

Here the treatment would depend on the dilatibility of the cervix, the amount of placental tissue involved, the amount of blood lost by the patient, etc. If the cervix were soft and the edge of the placenta near enough the os to allow us to push it to one side, we could use a rubber dilating bag, or do a version and extraction. If the cervix were rigid, the hemorrhage considerable, or the edge of the placenta out of reach of our finger, we would get better results for both mother and child by a Cesarean.

A central implantation I consider to be an absolute indication for Cesarean except under unusual circumstances. This would apply more particularly to primipara with rigid cervix.

In the less serious conditions the best results will be obtained for both mother and child by the use of the rubber bag rather than the more popular version. For version, using the baby as a dilating wedge, while giving as favorable a maternal mortality as the bag causes the death of most infants.

Cesarean section, if used in central implantation and in some of the complete variety, will give a much lower mortality than if we use other treatment and allow our patients to become exsanguinated during the slower delivery. Whatever treatment is chosen the fetal mortality will always be considerable as many of the infants are premature or weak from loss of blood.

**Concealed Hemorrhage from Separation of Normally Implanted Placenta**—Most of these we see are not especially serious and may safely be treated as we would treat a mild degree of placenta previa, by dilating the cervix with a hydrostatic bag. Williams and Couvelaire have reported a number of the extremely dangerous type in which the body of the uterus has undergone degeneration and refuses to contract. The diagnosis is made on the rigidity and boardlike consistency of the uterus and a section should be done, followed by a hysterectomy.

**Eclampsia**—There have been many theories advanced as to the cause of this serious complication of pregnancy, and as many methods of treatment. Two of the most rational theories are First—an excess of cytotoxin (a protein poison originating from the fetus) circulating in the maternal blood and which is not neutralized by sufficient cytolyisin of maternal origin. The other theory is that it is an excess of the products of maternal and

given as the reason for operating, among these being absolutely contracted pelvis, contracted pelvis (border-line cases), disproportion between fetus and pelvis, contracted outlet in funnel pelvis, habitual fetal death in labor, prolapsed cord, tumors obstructing birth canal, stenosis of cervix from scar tissue or cancer, eclampsia, preclampsic toxemia, placenta previa, concealed hemorrhage from separation of normally implanted placenta, cardiac decompensation with complications, edema of vulva, face, brow, occiputposterior, and transverse presentations, mother nervously unfit.

In this long list there are a few very definite indications, a number of allowable indications, more of very hazy indications and some that are indefensible.

I will take these up separately, but briefly.

*Absolutely Contracted Pelvis*—About this condition there is little argument and Williams states that "a true conjugate of less than 7.5 cm renders the spontaneous birth of an ordinary full term baby impossible, though it is possible after a craniotomy."

*Contracted Pelvis (Border-Line Cases)*—These would be the cases with a true conjugate above 7.5 cm, and here the obstetrical judgment and individual preference of the attendant comes into play. With some who are also gynecologists or do considerable obstetrical surgery, their mind may be more or less biased by their knowledge of what can be safely accomplished by surgical means. Others who do no surgical work at all, but who have attained a high degree of skill in delivering difficult cases by forceps or version are naturally prejudiced in favor of this method of procedure. To my mind, the course to follow in this class of cases is to weigh the evidence of our findings pro and con, and to decide by what shows to the greater advantage and safety of mother and child.

This evidence consists of careful and painstaking pelvic measurements, position and presentation, size of child and ability to engage the presenting part if a vertex, the amount of flexion, and compressibility of the head.

Our obstetrical judgment based on these findings can only be of value if built on careful observation of the delivery of a large number of such cases. For how often we see a case in which we had feared a difficult labor, go through with no trouble, or at the most a low application of forceps. A few cases have been reported of women delivering themselves spontaneously while being prepared for Cesarean. These were probably cases in which the pelvic measurements might have forecast trouble, but in which the attendant had not taken into consideration the size of the child or the compressibility of its head.

The estimation of the size of a child at term is of greatest importance, and while it can never be anything but relative, one can by an antepartum

estimate in every case he sees come to a fair degree of skill.

There is no argument in the border-line case as to the possibility of Cesarean section, for we know that we probably will get both a living mother and child. But at the same time we must consider the maternal morbidity and mortality, small as it is, and also the effect of the operation on subsequent labors. This I will take up later.

On the side of delivery through the birth canal we must consider not only the possibility of delivering a living un mutilated child through undamaged soft parts, but we have to realize the possibility of cerebral injury and of nerve lesions due to difficult forceps or version. Too often we see in our own, or in the practice of others, still born babies, mental defects from brain injury, fractured humerus or clavicle, or birth palsies, all due to a mistake in our judgment.

It is poor obstetrics to do a Cesarean because we have the opportunity, because it is easy and simple, or because we can persuade ourselves or the patient that it is permissible on account of a slightly contracted pelvis, but it is also poor obstetrics to drag a child through a small pelvis by forceps or version simply to demonstrate our ability to do it. As someone has said, "It is possible to go through the Niagara whirlpool in a barrel, but not advisable." These border-line cases should be decided by trying to put aside our personal preferences or prejudice and deciding what is for the best interest of the mother and next for that of the baby.

If we cannot come to a definite decision, I consider it permissible to allow the test of labor for a limited number of hours hoping that the head will engage. This can be done safely by avoiding vaginal examinations (with the exception of one to estimate the conjugate vera) and obtaining our information of progress from abdominal findings.

If then we find the head unable to engage after molding we can operate, while if the head does engage we can let labor proceed, and we have saved the patient an unnecessary surgical operation.

*Disproportion Between Fetus and Pelvis*—Here we have practically the same problem to meet as in relatively contracted pelvis. Occasionally these very large babies are overtime and any woman who goes past her expected date of confinement should be seen frequently and the size of the baby estimated carefully. If the baby seems to be above the average size or as large as would seem safe for the given pelvis, labor should be brought on.

*Contracted Outlet*—The funnel type of pelvis is more common than is generally supposed, and many of the women who give a history of low forceps in their labors belong to this type. Fortunately we do not see many of the badly contracted outlets. They may cause serious trouble in delivery, however, and if the distance between

the tubera ischii measures less than 8 cm the anterior and posterior sagittal should be estimated. If the posterior sagittal falls short it is better to do a Cesarean than to subject the baby to the danger of cerebral hemorrhage from a difficult forceps extraction. As has been aptly pointed out, "It is sometimes easy to get a head into a pelvis but difficult to get it out."

*Habitual Fetal Death in Labor*—We should do our best in these cases to determine the cause of the previous deaths, by Wassermann reaction, careful exploration of the pelvic cavity, etc.

If we are unable to ascertain the cause and are, therefore, unable to correct it, I feel that these women are entitled to Cesarean section to obtain a living child.

*Tumors Obstructing Birth Canal*—Tumors obstructing the birth canal form a more or less definite indication for section. These may be uterine fibroids, or the various solid or semisolid ovarian tumors, but as they often become gangrenous from labor pressure or torsion of the pedicle, it is safer for the mother not to subject her to the risk of labor. In this instance, the low or median incision should be used and the tumor removed, if pedunculated, after the uterus is closed. Nonpedunculated uterine fibroids may be removed before pregnancy or fairly early in it, but at term they are not a cause for Cesarean unless obstructing the canal and could be removed between pregnancies if thought best. A pedunculated tumor may be a cause for section for fear of torsion, whether obstructing the canal or not.

*Prolapsed Cord*—This complication in a multipara should practically never be cause for section. In nearly every case the cervix could be dilated, manually, rapidly enough to permit the delivery of a living child by version. In a primipara with rigid cervix it may be justifiable, but here it is entirely in the interest of the child, and the case should be stated clearly to the parents, leaving the decision with them.

*Placenta Previa*—To make a statement positively that placenta previa should or should not be treated by Cesarean section is irrational. There are so many factors differing in different cases that the treatment of the one in hand would have to be decided on what presented in that particular instance.

No one would agree that all placenta previa should be treated by section, and certainly no one should say that no placenta previas should be so treated. The ordinary classification of placenta previa is that of marginal, or only a slight encroachment on the cervix. Partial, or the os partly covered by placental tissue. Complete, the os completely covered. Central, the os not only completely covered, but near the center of the placenta.

The marginal or partial varieties usually cause

us but little anxiety or trouble, and often as simple an expedient as rupturing as membranes and allowing the head to come down on the detached area will arrest the bleeding. If this does not accomplish it, a Voorhees hydrostatic bag will almost certainly do the work, and at the same time give us the much desired dilatation for delivery.

A complete placenta previa is a much more serious affair and often taxes the skill of the accoucher to the utmost.

Here the treatment would depend on the dilatability of the cervix, the amount of placental tissue involved, the amount of blood lost by the patient, etc. If the cervix were soft and the edge of the placenta near enough the os to allow us to push it to one side, we could use a rubber dilating bag, or do a version and extraction. If the cervix were rigid, the hemorrhage considerable, or the edge of the placenta out of reach of our finger, we would get better results for both mother and child by a Cesarean.

A central implantation I consider to be an absolute indication for Cesarean except under unusual circumstances. This would apply more particularly to primipara with rigid cervix.

In the less serious conditions the best results will be obtained for both mother and child by the use of the rubber bag rather than the more popular version. For version, using the baby as a dilating wedge, while giving as favorable a maternal mortality as the bag causes the death of most infants.

Cesarean section, if used in central implantation and in some of the complete variety, will give a much lower mortality than if we use other treatment and allow our patients to become exsanguinated during the slower delivery. Whatever treatment is chosen the fetal mortality will always be considerable as many of the infants are premature or weak from loss of blood.

*Concealed Hemorrhage from Separation of Normally Implanted Placenta*—Most of these we see are not especially serious and may safely be treated as we would treat a mild degree of placenta previa, by dilating the cervix with a hydrostatic bag. Williams and Couvelaire have reported a number of the extremely dangerous type in which the body of the uterus has undergone degeneration and refuses to contract. The diagnosis is made on the rigidity and boardlike consistency of the uterus and a section should be done, followed by a hysterectomy.

*Eclampsia*—There have been many theories advanced as to the cause of this serious complication of pregnancy, and as many methods of treatment. Two of the most rational theories are First—an excess of cytotoxin (a protein poison originating from the fetus) circulating in the maternal blood and which is not neutralized by sufficient cytolsin of maternal origin. The other theory is that it is an excess of the products of maternal and

ng serious results either immediate or remote.

One great aid in lessening the strain and physical suffering and in adding to our patient's safety is the use of morphine and scopolamine during the first stage. This with other aids, such as dilatation of the cervix, forceps, or version, in favorable cases will carry many to a favorable conclusion. Mackenzie gives a poor prognosis in mitral stenosis or aortic regurgitation.

There will still remain a small number of cases of decompensation where none of these maneuvers will give us a sufficient margin of safety. In these would be the primipara with rigidity or some complication, such as malpresentation or disproportion between fetus and pelvis, where I feel that we are justified in delivering by abdominal section under gas-oxygen anesthesia or under local anesthesia.

I would like to briefly call to your attention the use and value of local anesthesia in cases of eclampsia, diabetes, or decompensated heart. In cases who cannot stand an anesthetic I use about half a dram of 1 per cent novocaine solution, about half an inch from each costal margin, going deeply enough to feel your needle through the fascia. Another half dram just medial to the anterior superior spine of the pelvis, to catch the ilioinguinal nerve. Thus you have blocked most of the nerves supplying the abdominal wall, but it is best to also make a generous incision in the skin at the site of the incision. By covering the patient's eyes and by having a nurse sit at the head of the table and engage her in conversation, she will go through with practically no pain or mental distress, but is apt to complain of a disagreeable sensation of dragging as the baby is brought through the incision. For the same reason she will complain if you put much traction on the peritoneum or other tissues.

Of course, this procedure will not compete with anesthesia in the ordinary case, but is of great value occasionally. I have five such cases to report, all successful and practically painless. One, a diabetic, one, a diabetic and nephritic, and three cases with decompensated hearts.

The remainder of indications listed earlier I shall group together as "Indefensible indications for Cesarean Section." These are edema of the vulva, face, brow, occiput posterior, and transverse presentations, and mother nervously unfit.

Edema of the vulva can practically always be reduced by purging and diet, or by multiple puncture. The different malpositions such as face, brow, occiput posterior, and transverse should be amenable to skillful obstetric manipulation.

The reason that a mother is nervously unfit to undergo labor seems to me to be a far cry. Personally, I should be inclined to carry such a case

through labor with the help of morphine and scopolamine, or some other sedative.

In taking up the danger of rupture of Cesarean scar, I can do no better than to quote the conclusion of Dr. Palmer Findley of Omaha, Nebraska, who has analyzed sixty-three reported cases. There are many able men who abide by the dictum "Once a Cesarean, always a Cesarean," but many of us have delivered cases by the natural passages, following a Cesarean, and Findley's opinion based on so large a series should bear great weight.

He said "When Cesarean section has been followed by a fever course, the uterine wound should be regarded as insecure in event of a subsequent pregnancy and should call for a repeated section at the onset of labor. A perfectly healed Cesarean wound may be relied on to resist the forces of labor, but in view of the fact that the integrity of the wound is an unknown factor in all cases, we are constrained to exercise the utmost caution and calling for masterly control in the conduct of every case in pregnancy and labor following Cesarean section. The liability of rupture is a real danger and should stand as an argument against the increasing tendency to widen the scope of elective Cesarean operations."

The types of Cesarean most commonly used in this part of the country are first, the "High Davis" with its small incision above the umbilicus, second, the so-called "Classical" with its generous incision below the umbilicus, third, the low cervical with its incision just above the pubis. The extra peritoneal operation is rarely done as the technique is difficult and on account of tearing of the peritoneum is apt to become intra-peritoneal. The new extra peritoneal operation as described by Brodhead before this section last year sounds simple and logical, though personally I have not had the necessity of using it in an infected case as yet.

The High Davis and the Classical operation enjoy a well-deserved popularity in cases before or early in labor, but should not be used late in labor, in cases with ruptured membranes, or where there has been frequent examination or attempted interference. It is in these cases where we may safely use the low cervical operation. Its technique is slightly more difficult and time-consuming, but its greater factor of safety far outbalances this. The extra peritoneal might be reserved for frankly infected cases, and here would be safe where other types of operation would be most dangerous.

Dr. Rudolph Holmes, in expressing his views of the increasing frequency of Cesarean section has written an article entitled "Obstetrics, a Lost Art," and while I feel that this is an extreme view to hold, it might well be justified if the present furor for Cesarean section continues to grow.

## RABIES AND ITS CONTROL\*

By VERANUS A. MOORE, M.D., V.M.D.

Dean, New York State Veterinary College at Cornell University, Ithaca, N. Y.

**R**ABIES, or hydrophobia, is an acute, specific infectious disease of animals and man. It is characterized by an incubation period of variable length, nervous disorders, extreme reflex excitability, followed by paralysis, the absence of gross lesions by which its identity can be assured, specific microscopic changes in the brain, and exceedingly high mortality. Its etiology has not been determined positively, but it is known to be a filterable virus. All mammals may be infected and certain birds are reported to be susceptible.

Historically, rabies was one of the first specific diseases to be described. Aristotle described it in the fourth century B. C. He wrote, "Dogs suffer from madness that puts them in a state of fury, and all the animals they bite, when in this condition, become also attacked by rabies." Notwithstanding, many people, including some medical men, question its existence. The name "hydrophobia" (fear of water) was assigned to human rabies by Cornelius Celsus, who lived in the early part of the Christian era.

Geographically, it is widespread, being known to have existed in nearly every country on the globe. It was brought to America about the middle of the 18th century. It spread gradually throughout the United States and Canada. It continues to exist in these countries in more or less restricted areas which are changing constantly as the infection spreads to new territory and disappears from the old.

Pasteur pointed out that its virus gains entrance to the tissues through wounds, infected with the saliva of rabid dogs, and that it becomes localized in the central nervous system. The virus travels to the brain through the nerves or lymphatics immediately surrounding them. It escapes from the body with the saliva. The extent of its presence in other secretions or excreta has not been determined. Nocard found that glycerin, which destroys most bacteria, is an excellent preservative for the virus in brain tissue. It will remain virulent in this medium for several (three to four) weeks.

In 1903, Negri discovered peculiar structures in the cytoplasm of brain cells and suspected them to be of etiological value. Williams gave them the name *Neurorrhycles hydrophobae* and pointed out definite reasons for placing them among the protozoa and for believing them to be the specific cause. Kelser states that his studies "lend support to the contention that they are a type of protozoan organism primarily responsible for the disease." The description by Manouelian and Viala of structures in the nerve cells which they call *Encephalitozoon rabiei* are not yet

clearly differentiated from Negri bodies. Other workers have considered them products of degeneration. Kraus, Gerlach and Schweinburg, in their recent volume of *Lyssa*, place much emphasis on the value of Negri bodies in the diagnosis of rabies. They give numerous methods for demonstrating and differentiating them from other known cell inclusions. Their presence is considered evidence of rabies.

The natural mode of infection is through the bite of rabid animals. Because of the proneness of dogs to bite, the infected canine is the chief factor in its spread. It is not necessary to dwell on the syndrome of rabies in this species, for it is described fully in modern textbooks on infectious diseases.

In the prevention of rabies the diagnosis is of first importance. It is difficult, and often impossible, to determine positively the presence of the disease from the symptoms, especially in its early stages. The two types of rabies, namely, the "dumb" and the "furious" forms, are not distinctive in all cases. Porcher has pointed out that glycosuria is a characteristic symptom, and Coakley has called attention to the pin-point contraction of the pupils as a manifestation of much value. However, these are not always easy to recognize, and, further, they are said to be absent in some cases. The changes in the brain described by Babes and Golgi are often difficult to find. The cellular proliferation in the peripheral ganglia of the cerebro-spinal and sympathetic systems, pointed out by Van Gehuchten and Nehls, is not always in evidence, especially if the suspected animal is killed in the early stages of the disease. Frothingham found that these changes sometimes occurred in one ganglion and not in another. The subdural, or intraocular, inoculation of rabbits, or other animals, with suspensions of the brain is not satisfactory because of the long and variable period of incubation. This is particularly true when people have been bitten and a diagnosis is wanted to direct the treatment. It was, therefore, a great step forward when Negri bodies were proven to be of dependable diagnostic value. Their detection in brain cells is considered positive evidence that the animal or person from which they came had rabies or had been infected with its virus. These bodies may appear in the brain of an infected individual several days in advance of recognizable symptoms, and the saliva may be infectious for an appreciable time before symptoms are in evidence.

In the practical handling of an outbreak of this disease all dogs, and possibly other species, exhibiting suspicious symptoms should be destroyed and their brains examined for Negri bodies. When symptoms are absent, the suspected dogs should be confined under close ob-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927.

servation, to ascertain whether or not they are in the period of incubation. If the dog remains well for several (5 to 15) days, the chances that it transmitted the virus are exceedingly slight. On the other hand, if the dog is about to come down with the disease, and its bite is liable to transmit the virus, it will exhibit symptoms in a few days when it can be destroyed and the diagnosis made. In most cases this can be done in time for those who have been bitten to be given the preventive treatment. Should the bites be about the head and shoulders, the treatment should be administered promptly. Pure nitric acid applied immediately to small wounds is a very effective disinfectant.

The methods for demonstrating Negri bodies are described clearly in our laboratory manuals and are well understood by technicians. It is recognized, however, that great care should always be exercised in doing the work. From the point of view of control, prompt diagnosis is of first importance. It enables people who have been bitten to take preventive treatment, and, likewise, it gives sanitary officials time to enforce regulatory measures to prevent subsequent cases.

In any effort to control rabies it should be recognized that people should be made to understand, in a general way at least, the necessity for the enforcement of preventive measures and the reasons for them. Before the public can become reconciled to regulatory supervision of their pets, the physicians and veterinarians, who are their immediate advisers, must be familiar with the problem. We have witnessed outbreaks that were prolonged and the number of cases increased unnecessarily because the professional men to whom the owners appealed for help were as skeptical and bewildered concerning the malady as the laymen themselves. Such a situation reminds one of the "blind leading the blind."

An inquiry into the prevalence of rabies in the United States shows that it is a more formidable destroyer of life than is supposed. Prior to Pasteur's discovery of a preventive treatment, it was the cause of many deaths in Europe. Until quite recent times there seems to have been little, or no, data relative to its presence in this country other than statements that at different times serious outbreaks had occurred. In 1884, Salmon found that it was widespread in the United States. The census of 1890 recorded 143 deaths in man, scattered over thirty different states. Kerr and Stimson found that, in 1908, 111 people died of rabies in the United States and that it had existed among domesticated animals in 534 localities. The states which contained the largest number of areas in which the disease existed were Wisconsin, Illinois, Virginia, Maryland, Delaware, New Jersey and New York. The losses among animals in Wisconsin were estimated by the state veterinarian to be 400 cattle, 100 hogs, 56 horses and 28 sheep. Nelson, Chief

of the Biological Survey, U. S. Department of Agriculture, called attention, in 1917, to the great damage caused by rabies among predatory animals in Nevada, California, Idaho and Utah.

In 1921, T. F. Sellers, Director of the Georgia State Board of Health Laboratories, found that rabies existed in 29 states and that a total of 5,558 heads had been examined for diagnosis in official laboratories and that 2,699 of them were positive. Further he learned that there had been 168 cases of rabies in man from 1917 to 1921, and that 26 of these had occurred during and after the Pasteur treatment. In 1924, Eichhorn presented the data on its existence which he had gathered by means of a questionnaire sent to state laboratories. He received 34 replies and the information they contained is given in the appended table.

Year	No of Positive Examinations made in State Laboratories	No of Persons Given Anti rabies Treatment	Human Deaths
1920	1,506	3,350	25
1921	2,005	4,567	35
1922	2,522	6,041	34
1923	2,705	6,110	37

In recent years, rabies has been reported more frequently in the southeastern and southwestern states than elsewhere in the country, although it has existed in several areas in other states. Fifteen years ago it prevailed extensively in the northeastern part of the United States. The information we have relative to its distribution indicates that it is still widespread, appearing here and there in more or less isolated areas, and spreading from these centers.

The dissemination of rabies in New York State, outside of New York City, from 1898 to 1926, is both interesting and instructive. At first, there were a few cases in the Hudson River Valley. The number increased steadily for two years in and about Albany. Gradually it extended westward, following the main highways and railroads and establishing foci in the larger cities. It radiated from this westerly course to the north and to the south, again following the usual routes of travel. The number of examinations made at our laboratory for diagnostic purposes increased from a very few in 1898 to 588 with 295 positive specimens in 1908\*. Since that time the number dropped annually until 1923 when there were but 36 examinations with only four positive cases. In 1926, there were 74 dogs' heads examined of which 26 were positive. This increase in number marks the beginning of another series of outbreaks, again beginning in the lower part of the Hudson River Valley, and spreading as before in a westerly direction. Wil-

\* The authority for the control of rabies in New York State was vested in the Commissioner of Agriculture and practically all of the specimens for diagnosis outside of Greater New York were sent to the New York State Veterinary College for examination. In 1925 the legislature transferred the control of rabies to the Health Department. Since that time examinations have been made in several laboratories.

liams reported for 1926 in New York City a total of 888 examinations for rabies of which 462 were positive. This was an increase of 377 examinations over the previous year. In her report, attention is called to the significant fact that 128 of these specimens were classed as stray dogs.

We are interested especially in the control of rabies. As it is disseminated through the bites of rabid animals, and as the dog is the one domesticated animal, possessed of a natural tendency to bite, the control of rabies in dogs circumscribes the problem so far as it concerns public health officials. There is a large literature on rabies in wild animals but in the greater part of the thickly populated sections of this country its spread to man by such animals is negligible.

The prevention of rabies involves one of two procedures, namely, keeping the virus away from our dogs, or immunizing them against it. The procedure that has been employed with varying degrees of success in local communities for keeping dogs from becoming infected is *the enforcement of general quarantine*. It involves the elimination of homeless dogs, and the rigid application of the muzzle, or the leash. When there is full cooperation between dog owners, members of the medical professions, and health officers, this procedure is very satisfactory. It is being followed under some form of regulation in practically every state. The failures have been due for the greater part, to laxity in the enforcement, makeshifts for muzzles and placing too small an area under quarantine. The quarantine area should be large enough to include the territory covered by the wandering, rabid dog. The procedure demands prompt diagnosis, the destruction of all animals that have been bitten by the rabid dog, or placing them under close observation and the *elimination of stray and homeless canines*.

One of the practical difficulties is the tendency of affected dogs, especially those with the furious form, to wander from home. They often travel long distances (30 to 40 miles) before death ends the struggle. Usually such dogs "jog" through the country on a "dog trot" and if not disturbed ordinarily do little harm, but, if they are attracted by moving people or animals, they are liable to bite. This is why stray, or loose, dogs are more apt to be bitten and why they present the greatest opportunity for the disease to spread. The bitten dogs become new centers of infection from which still other cases may arise. This explains why the quarantine of small areas, like villages, is inadequate.

While the preventive treatment introduced by Pasteur has been successful in man, it is too expensive for the practical immunization of all dogs. To overcome the objection of repeated doses required by the Pasteur method, many researches have been made to produce a single-injection vaccine for immunizing dogs.

Umeno and Doi produced a vaccine by keeping an emulsion, prepared by grinding the central nervous tissues of a rabbit, dead from fixed virus, in a mixture of sixty parts of glycerol and forty parts of 14 per cent phenol and holding it for two weeks at room temperature. They reported that in 104,629 dogs in Tokyo and Yokohama that were treated with it, only forty-one cases of rabies occurred, while 1,699 cases appeared among the unvaccinated dogs. Kondo prepared a single vaccine from the brains of rabbits, inoculated with a fixed virus, and exposed to different temperatures. It was applied to 20,117 dogs in Hokkaido, Tokyo, and ten other prefectures from June, 1919, to February, 1921, and with the exception of four dogs that died within a week from natural infection, contracted prior to vaccination, no cases of rabies were reported for a period of one year. Kondo makes the following summary of his work:

(1) "Of various vaccines which were prepared and tested on animals in the laboratory the one prepared by incubating the emulsion of the brain and cord from animals infected with a fixed virus at 37°C for three days, or that prepared by keeping the emulsion at room temperature for ten days, is most applicable for the vaccination in the dog.

(2) "The vaccine prepared by incubating the emulsion at 37°C is better than that prepared by keeping it at room temperature because more uniform attenuation of the virus could be expected in the former treatment.

(3) "In the dog the vaccine is to be once inoculated subcutaneously in doses of 5 cc.

(4) "For the source of the vaccine, the brain and cord of the dog are better than those of the rabbit because the yield in the former is six times more than that in the latter.

(5) "The immunity produced by the vaccine lasts for but one year."

In 1926, Kondo states that the official statistics of the Japanese Bureau of Animal Industry show that the total number of animals vaccinated from 1918 to 1925 was 755,270, consisting of 755,072 dogs, 115 cattle, 69 horses, 2 hogs, 7 sheep and 5 goats. Of the treated animals 170 dogs, 5 cattle, 2 horses, 4 sheep and 2 goats, developed rabies within one year.

A large amount of research work on the preparation of a single-dose vaccine has been done in this country. Eichhorn and Lyon conclude from their work that dogs can be immunized experimentally by a single-injection method and that in practice their laboratory results are confirmed. They state that "thus far they include statistics on about 2,500 dogs which have been given the single-vaccine against rabies. None of these animals developed the disease." They state further that "No data is available to establish how many of these animals were exposed to the disease."

Reichel has shown that dogs can be protected by the single-injection vaccine against inoculation with a fixed virus. A few experiments made in my department confirm his results.

The control of rabies through annual vaccination of dogs by a single-dose vaccine is a hope of sanitarians. There are at least a few, and perhaps many, people who would welcome a uniform law requiring the annual vaccination of all canines. The last report from Kondo suggests that the Japanese have a method of preparing a vaccine that will be satisfactory. As there are apparently several strains of street rabies virus, it is not clear whether a vaccine that will protect against its own antigen will immunize dogs against the strain of street virus they may be infected with through the bites of rabid dogs. The statements from several health officials indicate that the vaccination of dogs has given excellent results but, unfortunately, they do not mention the normal incidence of rabies in the communities where the method has been applied.

On the other hand, we are told by a few laboratory men and sanitary officers that dogs that have been vaccinated and later exposed, have developed rabies and died. Dr Church, Deputy State Veterinarian of Pennsylvania, tells us of several unfavorable experiences with the single-dose vaccine. Dr E P Savage of Weslaco, Texas, states, in a letter to our laboratory, that a dog that had been vaccinated at the base of the skull with single-dose vaccine developed rabies. Also, he affirms that if the full dose of vaccine is injected in one place, in the region of the body mentioned, it will cause hydrophobia. Schoening carried out a series of experiments in the Federal Bureau of Animal Industry on the immunization of dogs against rabies by the single-dose vaccine method. He pointed out the existence of two or more strains of rabies virus and showed that vaccination against one strain did not immunize against the other. For example, he obtained distinct protection against intra-ocular inoculation with one strain in 12 out of 16 vaccinated dogs, but with a different strain of street virus (B. A. I 474) practically no protection was afforded the treated animals.

A further point to be determined is the length of time immunity induced by vaccination will last. The Japanese do not place it beyond one year. Meissner and Baars found the immunity to last from 8 to 14 months. Fortunately, we do not have any community in the United States where the normal incidence of rabies is sufficiently high or constant for a practical test of the efficiency of this method. For that reason the value of vaccines must be determined experimentally. To do this on a sufficiently large number of dogs to render the results trustworthy is both a difficult and an expensive task. To recommend the control of rabies by the universal vaccination of dogs, with a vaccine at best of questionable efficiency, would be most unfortunate. The moment

the idea of protection by immunization is accepted by the public all other precautions will be deemed unnecessary and most likely abandoned. If the method should fail, it would become a serious menace rather than a protection.

Finally, from the success in the control of rabies that has been obtained by rigid quarantine the following conclusions seem to be justified, until more extended knowledge of the subject may indicate a different procedure.

- 1 That the practice of making an early diagnosis and the enforcement of *rigid quarantine* be continued in all communities where rabies exists.

- 2 The small, normal incidence of rabies in any locality in the United States, does not justify the annual, compulsory vaccination of all dogs as the sole means of control.

- 3 In localities where rabies exists, the vaccination of all dogs might give additional protection. However, it should *not* be used as a substitute for the enforcement of rigid quarantine but in conjunction with it.

- 4 The results that have been recorded from the use of single-dose vaccines do not justify health officers, or live stock sanitary officials, in relying solely on this method for the control of rabies.

- 5 The degrees of success that have been attained experimentally, both in this country and in Japan, in producing an immunizing vaccine against rabies, give encouragement that eventually a single-dose vaccine may be discovered that will protect against all strains of rabies virus.

## DISCUSSION

In answer to questions, Dr Moore said. I do not know how the misunderstanding of many people concerning rabies can be corrected unless it is by personal instruction given them by their physicians and veterinarians. The funds collected by means of a tax could be diverted to the elimination of homeless dogs and a study of rabies and other diseases if the legislature would pass a law requiring it. Our law makers might encounter some difficulty in attempting such legislation, but it should be enacted.

The inoculation of rabbits with dogs' brains for making a diagnosis of rabies before the person bitten takes the preventive treatment is questionable because of the long and variable period of incubation. If one is bitten badly about the head or shoulders and there is reason to suspect the dog has rabies, the Pasteur treatment is indicated. It is not often that rabies exists and Negri bodies can not be found.

It is my understanding that the virus travels from the point of infection to the central nervous system through the nerves or the lymphatics immediately surrounding them. A number of cases have been reported where the saliva of a rabid dog had come in contact with abrasions, and

where it appears that there were no recently injured nerves. If such cases are genuine, either the hypothesis of infection is wrong or the injured nerves were still permeable to the virus.

## COOPERATION BETWEEN INTERNIST AND SURGEON IN HANDLING BILIARY TRACT CONDITIONS\*

By JOHN A. LICHTY, M.D., AND CHARLES W. WEBB, M.D., CLIFTON SPRINGS, N. Y.

THE work of Graham, Mann and others for the past nine or ten years has brought new stimulus into the study and handling of hepatic conditions. It might be said that up until ten years ago about the only study of biliary tract cases was the history and physical findings and it was considered almost exclusively a surgical condition. Today with the extensive development of chemical methods, X-ray and laboratory studies we find internists keeping these cases on their service much longer and the case coming to the surgeon with the diagnosis already made. Such a tendency often leads the surgeon to operate soon after the case is transferred to his service and he has probably come into contact with the patient hardly enough to make a good estimate of the patient's symptoms compared with the risk of an operation. Therefore, at Clifton Springs we try to follow the plan of the surgeon and internist seeing the patient frequently, conferring on the data and coming to a joint conclusion regarding the treatment.

We make a distinction between the diagnosis of medical and surgical diseases of the biliary tract on account of the fact that certain disturbances of the gall bladder and ducts may be of such a nature that the mechanical interference which surgery implies may not be necessary. In such conditions, a course of treatments, or a regime, usually called medical, may be advisable which does not include the administration even of medicines, but covers simply care as to diet and as to certain principles of hygiene. This distinction between medical and surgical diseases cannot always readily be made but it is a necessary one.

The diagnosis of any disease, and its intelligent interpretation, depends largely upon the recognition of the progress of the pathology, as evidenced by the chronological order of the appearance of the symptoms and signs. In such diseases as malaria, typhoid fever and syphilis, on account of the specific etiological factor, the disease may be readily named, but named only, whereas in disease of the biliary tract, the specific diagnosis implies the extent of the invasion of the disease. As already stated, this determines whether the condition is to be approached from the medical or from the surgical standpoint.

The early symptoms of biliary tract disease may be most insidious, and apparently inconsequential, or they may be most fulminating and tragic.

### HISTORY

Of the insidious symptoms the following are of importance.

1 Gas, or abdominal flatus. Now it is well known that gas is a normal content of the gastrointestinal tract, the same as chyme or chyle and feces are. The chemical and fermentive process of digestion cannot proceed without the formation of gas. It is also known that a patient may by a slight physical effort and a little mental aberration persuade himself or herself that there is an excess of gas in the stomach and bowels. Aerophagia is not uncommon among a certain class of patients. But gas is not the real condition of which the patient complains. The patient who complains of gas really complains of a group of symptoms which he naturally interprets as being caused by the presence of gas. These symptoms are pressure in any part of the abdomen or chest, demonstrable distension of the

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927.

abdomen and frequently more or less pain. To accept the statement from the patient suffering from "gas on the stomach" without a purposeful analysis of the symptom complex implied is likely to lead to a wrong diagnosis because it may be the temporary effect of an unfortunate selection of food, or it may be the result of definite pathology.

**2 Pain** This may be only a slight discomfort anywhere in the abdomen or chest, relieved by a glass of hot water, or it may be so severe as to require repeated hypodermics of morphine. It may also be definitely localized at the ninth cartilage of the right costal margin and referred to the right scapula, or to the precordia or elsewhere. The pain may come at any time in relation to meals, frequently occurring after midnight and with the evidence of a physical disturbance somewhere in the lower biliary tract. It may be caused by only a muscular spasm, or by an acute flare-up of a focus of infection, or it may be the result of the movement of a stone. The more severe the pain the more likely it is due to stone. The pain is reflected along the right costal margin sometimes to the right scapula. It may be referred to the precordia. Such an attack, be it mild or severe, usually affords an opportune time to obtain certain data which may be very important. That is to say it should be determined whether there is localized tenderness in the region of the gall bladder, an elevation of temperature, an increase in the white blood corpuscles, the appearance of bile as well as sugar in the urine, the color of the stools and the evidence of icterus. These observations should be made at once and repeated for several days after the attack.

**3** The so-called "*bilious attacks*" of which the patient frequently complains, may be any condition from a sick headache to an acute pancreatitis and it should therefore, never be accepted without careful analyses. With these bilious attacks there is loss of appetite, nausea and sometimes vomiting. There may also be headache. The critical analysis of these three groups of symptoms, gas, pain and the so-called bilious attacks, may provide all the history available especially if the history of previous illnesses, such as certain infectious diseases, or certain digestive disturbances are included.

#### PHYSICAL EXAMINATION

A physical examination done at the time or immediately after an acute attack, usually gives more definite information than one done during the interval. In this examination the color of the skin and of the urine should be noted.

Chemists tell us there are no really reliable tests for bile in the urine. There is one bit of information, however, which can be easily obtained and has considerable significance and that is the yellow, or the bile stain, which may occa-

sionally be found on the linen of the wearing apparel or of the bedding.

Tenderness over the gall bladder area is frequently found, especially if the patient is shallow-chested and has a scaphoid abdomen. Otherwise, and especially when the gall bladder is contracted and lies up close to the spinal column a badly diseased gall bladder and common duct may escape detection.

#### LABORATORY TESTS

Certain laboratory tests should be instituted every time the symptoms are suspicious of an acute exacerbation. These have already been mentioned, such as examination of the urine for bile, of the blood, for the state of the leucocytes and the color of the serum. The Van den Bergh test and the icteric index may give confirmatory evidence, so may also duodenal drainage and an X-ray series of the gastro-intestinal tract.

There has been an extensive development during recent years of chemical methods designed to show whether the functions of the liver and gall-bladder tract are normal. As yet, most, if not all, of these methods lack satisfactory experimental confirmation. In fact, when they have been investigated under conditions which seem to be adequate—in Mann's classic experiments on totally and partially dehepatised dogs—it has been shown that the interpretation of the results is very difficult indeed. Therefore it seems certain that the clinician should be conservative in his own interpretation of such abnormal chemical findings as are made in the study of cases of this kind. There is no doubt at all that small deviations from the accepted normal values should not be emphasized unless they are in harmony with the general symptoms of the patient.

Our own attention has been largely centered upon tests for so-called "latent jaundice" and upon the relationship between bilirubin and urobilin in the urine. The demonstration of latent jaundice—the condition in which the concentration of bile in the blood is greater than normal, but where changes in the color of the skin cannot be made out—has received much attention in recent literature. The methods which we have used in studying this condition are three: 1 The measurement of the amount of yellow pigment in the serum (the so-called "icteric index"), 2 The presence of some compound giving the diazo reaction (the Van den Bergh reaction), 3 The production of a blue-green pigment when the serum is treated with ferric chloride in the presence of trichloroacetic acid (the "Fouchet test"). Of these only the last can be considered specific for bile pigments, and that one is not readily quantitated. We have, therefore, used the simplest, that is, the icteric index as an approximate measure of the pigment present, and have used the others to determine whether the yellow so measured was or was not due to bile. There seems to be a fairly definite relationship

between these tests upon which we will report later, and as a whole, we feel that this method has been fairly satisfactory. The interpretation of the findings, however, must be made conservatively, for among our chronic cases increases can be so frequently demonstrated that they must be due to various initial causes.

The second study upon which our attention has been centered is the relationship between bilirubin and urobilin in the urine. From every patient who enters the clinic at least one specimen of urine is obtained and these are tested for bile by the usual nitric acid method. This is a test for the pigment bilirubin, and when it gives positive results we then analyze the specimen for urobilin by the semi-quantitative method of Wallace and Diamond. In a very large proportion of the specimens so studied an increase in this latter pigment is demonstrated. This is interesting because McMaster has shown that urobilin is formed from bile pigment by the action of bacteria in the intestinal tract, and except for a few instances in which bacteria are present in the biliary tract in sufficient numbers to cause the change, is not formed in any other way. The logical conclusion from our results, therefore, is that in the greater part of our cases the presence of bile in the urine was not due to a partial or complete obstruction of the biliary tract, but to some other cause. This seems to confirm the conclusion reached from a study of the bile pigments in the blood, *i. e.*, that the interpretation of slight deviations from the normal circulation of bile pigments is not a simple matter.

Our experience with duodenal drainage as a diagnostic measure in suspected gall bladder and duct diseases has been somewhat varied.

#### X-RAY STUDIES

Our experience with the Graham test has been very satisfactory. Dr. C. Harvey Jewett, our Roentgenologist, in an analysis of one hundred cholecystographies, visualized the gall bladder in sixty-seven cases. In the cases which came to operation the conclusions arrived at were verified in 92.3 per cent of the cases. In this series of cases all of those which showed stones failed to visualize with the dye.

The oral method is followed in preference to the intravenous. The question of biliary tract disturbance can never be safely approached without having in mind certain other conditions which may be present in this region. Of these are particularly duodenal ulcer, pancreatic disease and stone or infection of the right urinary tract.

The diagnostic problem relating to biliary tract disease is comparatively easy. The suspicion of biliary tract disease may be entertained with the appearance of the mildest and earliest symptoms. If the physician is appreciative of the accumulative evidence which is furnished by history, physical examination and laboratory investigation, the fact of disease may be established. The

real problem in diagnosis comes, however, when the course of treatment is to be decided upon. Text books give a clean cut differentiation, specifying when a case, if it ever has been medical, becomes surgical, as follows: (a) repeated attacks, (b) the presence of a distended gall bladder attended with fever, (c) obstruction of the common duct, (d) persistent ill health (Osler). The Text-book on Surgery may declare that biliary tract disease is surgical as soon as its presence is determined, but this does not answer the question as to when the individual case is to be operated. This question involves the risk of operation. The operative mortality in different clinics varies as the proper technique is developed and perfected, and as the surgeon is willing to take a certain risk. How can this risk be estimated? Only by the routine careful study of every case. In this study particular attention is given to the heart. Babcock, Reisman and others have long ago called our attention to this. Not only should such methods of study as determine the degree of incapacity of the heart and circulation in general be instituted, but every effort should be made to re-establish a good compensation. A preliminary rest in bed, with careful diet and with digitalis, or other medication may be indicated.

The function of the kidney should be determined by well established and reliable tests. The choice of anaesthetics which is always a matter of concern, may depend largely upon the immediate functional capacity of the kidney. Preliminary dietetic, hydrotherapeutic and other measures may avert a catastrophe.

Studies which give information concerning carbohydrate metabolism are desirable. The close relation between the biliary tract and the pancreatic duct may cause a disturbance of carbohydrate metabolism so as to menace the operative risk to a large degree.

In a study of four hundred and thirty-one cases of biliary tract disease and of four hundred and fifty-five cases of diabetes mellitus, *Transactions of Am Gastro-Entero Ass* 1923 by Lighty and Woods, twenty-five patients were found to be suffering from both conditions. Diabetes mellitus as well as an increase of blood sugar, may and should receive such preliminary attention, through dietetic and other now well established lines of treatment, as to overcome this handicap.

The relation of the physician to the prospective operative biliary tract patient should be such as to develop a healthy optimism. These patients are inclined to be depressed to a degree that it may become a serious factor. The diagnostic study should include a consideration of this phase and a preliminary treatment should include measures to overcome it. The skill and ingenuity of the surgeon must be exercised to the full extent in these cases if the best results are to be obtained.

In an analysis of sixty-eight operations on the

gall bladder and tracts in the past two years at Clifton Springs, there were six deaths, a mortality of a little less than 9 per cent. In this series there were sixty-three excisions of the gall bladder and five drainage cases. It has been our custom to drain the sub-acute cases. The cystic duct was drained with a catheter in some of the cases where the pancreas was enlarged. The

pathological reports on the sixty-three cases of excision showed chronic inflammation in fifty-six cases. X-ray studies were made on fifty-six of these cases, but a cholecystography was done on only twelve of the fifty-six. In twenty of the cases flat plate and G I X-ray reports were negative for any pathology, but laboratory reports showed inflammation or stones.

## THE POSSIBLE RELATIONSHIP BETWEEN CONVULSIONS IN EARLY LIFE AND EPILEPSY\*

By WILLIAM T. SHANAHAN, M.D., SONYEA, N. Y.

Superintendent, Craig Colony

**O**BSERVERS have long sought to determine as to the relationship, if any, between convulsions in infancy and early childhood, convulsionosis, with epilepsy, convulsive disorders, in the adolescent or adult. If we accept what many contend, that epilepsy is rarely hereditary, we might expect that many convulsions are due to some fundamental enduring disturbance of the individual occurring in early life. Predisposing or precipitating factors to be considered are neuropathic heredity, parental syphilis and alcoholism damaging germ plasma, fetal maldevelopment, birth or subsequent head trauma, encephalitis and meningitis from infections such as scarlet fever, measles, etc., or mechanically as in pertussis, long continued metabolic disturbances, such as rickets, endocrine disorders and psychogenic abnormalities.

What constitutes an epilepsy? On what can a reasonable prognosis be based? While certain theories are attractively plausible, still they are but theories and must long remain as such. Our knowledge of the actual biochemistry of the central nervous system, as well as other vital organs and tissues, is meagre. What do we know regarding life processes of essential nerve cells? It has been advanced that epilepsy may be the result of a primary neuronc degeneration.

To show opinions of seventy years ago, I quote from West<sup>1</sup>, who mentions convulsions consequent to large loss of blood, that the brain in infancy is much more exposed to disorder than that of an adult, owing to the far wider variety of influences to which it is susceptible, and the frequency of convulsions in the young and the great variety of circumstances under which they occur, making it difficult to interpret their meaning. The cranium of the adult is a complete bony case and the firm substance of the brain affords a comparatively unyielding support to the vessels by which it is nourished. It is not so in

infants and the same causes which expose the brain to be overfilled with blood render it possible to be drained of blood more completely than in the adult. Convulsions take place in infancy not as result of any disease but simply in consequence of this anatomical peculiarity. West says it would not be right to attribute convulsions that sometimes occur at commencement of eruptive fevers entirely to derangement of the cerebral circulation, for something is probably due to changes in the blood itself. "The period of teething, like that of puberty constitutes one of the great epochs of life where changes are going on in the whole organism." "Convulsions in early life are unusual after the completion of dentition and warrant more serious apprehension in children of three or four years old than in infants of a year or eighteen months." "There seems to be a decided relation between the liability to convulsions in early infancy and development of epilepsy in subsequent childhood." He mentions that alleged causes of fits are not always the real ones, and stresses nodding spasms and petit mal in childhood continuing into a later epilepsy, mentioning momentary vertiges and attacks of apparently causeless alarm accompanied by incoherent talking. "The prospect of epileptic seizures ceasing at puberty is a very groundless one." "The severity of fits is of less importance in the prognosis of epilepsy than frequency of their occurrence. The oftener they occur, even in a mild form, the less is the prospect of their cessation."

Writers on dissimilar heredity in epilepsy give percentages varying from 1 to 87 per cent, differences so great as not to be satisfactorily explained except upon exceedingly incomplete data and including disturbances with little or no relation to nervous or mental disorders, thus much of what has been written regarding heredity in epilepsy and related conditions is without value from present day standards. Early writers discountenanced the admission of other nervous affections in ancestors as hereditary predisposing causes of epilepsy. In

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N. Y., May 11, 1927.

between these tests upon which we will report later, and as a whole, we feel that this method has been fairly satisfactory. The interpretation of the findings, however, must be made conservatively, for among our chronic cases increases can be so frequently demonstrated that they must be due to various initial causes.

The second study upon which our attention has been centered is the relationship between bilirubin and urobilin in the urine. From every patient who enters the clinic at least one specimen of urine is obtained and these are tested for bile by the usual nitric acid method. This is a test for the pigment bilirubin, and when it gives positive results we then analyze the specimen for urobilin by the semi-quantitative method of Wallace and Diamond. In a very large proportion of the specimens so studied an increase in this latter pigment is demonstrated. This is interesting because McMaster has shown that urobilin is formed from bile pigment by the action of bacteria in the intestinal tract, and except for a few instances in which bacteria are present in the biliary tract in sufficient numbers to cause the change, is not formed in any other way. The logical conclusion from our results, therefore, is that in the greater part of our cases the presence of bile in the urine was not due to a partial or complete obstruction of the biliary tract, but to some other cause. This seems to confirm the conclusion reached from a study of the bile pigments in the blood, *i. e.*, that the interpretation of slight deviations from the normal circulation of bile pigments is not a simple matter.

Our experience with duodenal drainage as a diagnostic measure in suspected gall bladder and duct diseases has been somewhat varied.

### X-RAY STUDIES

Our experience with the Graham test has been very satisfactory. Dr C. Harvey Jewett, our Roentgenologist, in an analysis of one hundred cholecystographies, visualized the gall bladder in sixty-seven cases. In the cases which came to operation the conclusions arrived at were verified in 92.3 per cent of the cases. In this series of cases all of those which showed stones failed to visualize with the dye.

The oral method is followed in preference to the intravenous. The question of biliary tract disturbance can never be safely approached without having in mind certain other conditions which may be present in this region. Of these are particularly duodenal ulcer, pancreatic disease and stone or infection of the right urinary tract.

The diagnostic problem relating to biliary tract disease is comparatively easy. The suspicion of biliary tract disease may be entertained with the appearance of the mildest and earliest symptoms. If the physician is appreciative of the accumulative evidence which is furnished by history, physical examination and laboratory investigation, the fact of disease may be established. The

real problem in diagnosis comes, however, when the course of treatment is to be decided upon. Text books give a clean cut differentiation, specifying when a case, if it ever has been medical, becomes surgical, as follows: (a) repeated attacks, (b) the presence of a distended gall bladder attended with fever, (c) obstruction of the common duct, (d) persistent ill health (Osler). The Text-book on Surgery may declare that biliary tract disease is surgical as soon as its presence is determined, but this does not answer the question as to when the individual case is to be operated. This question involves the risk of operation. The operative mortality in different clinics varies as the proper technique is developed and perfected, and as the surgeon is willing to take a certain risk. How can this risk be estimated? Only by the routine careful study of every case. In this study particular attention is given to the heart. Babcock, Reiseman and others have long ago called our attention to this. Not only should such methods of study as determine the degree of incapacity of the heart and circulation in general be instituted, but every effort should be made to re-establish a good compensation. A preliminary rest in bed, with careful diet and with digitalis, or other medication may be indicated.

The function of the kidney should be determined by well established and reliable tests. The choice of anaesthetics which is always a matter of concern, may depend largely upon the immediate functional capacity of the kidney. Preliminary dietetic, hydrotherapeutic and other measures may avert a catastrophe.

Studies which give information concerning carbohydrate metabolism are desirable. The close relation between the biliary tract and the pancreatic duct may cause a disturbance of carbohydrate metabolism so as to menace the operative risk to a large degree.

In a study of four hundred and thirty-one cases of biliary tract disease and of four hundred and fifty-five cases of diabetes mellitus, *Transactions of Am Gastro-Entero Ass* 1923 by Lichty and Woods, twenty-five patients were found to be suffering from both conditions. Diabetes mellitus as well as an increase of blood sugar, may and should receive such preliminary attention, through dietetic and other now well established lines of treatment, as to overcome this handicap.

The relation of the physician to the prospective operative biliary tract patient should be such as to develop a healthy optimism. These patients are inclined to be depressed to a degree that it may become a serious factor. The diagnostic study should include a consideration of this phase and a preliminary treatment should include measures to overcome it. The skill and ingenuity of the surgeon must be exercised to the full extent in these cases if the best results are to be obtained.

In an analysis of sixty-eight operations on the

gall bladder and tracts in the past two years at Clifton Springs, there were six deaths, a mortality of a little less than 9 per cent. In this series there were sixty-three excisions of the gall bladder and five drainage cases. It has been our custom to drain the sub-acute cases. The cystic duct was drained with a catheter in some of the cases where the pancreas was enlarged. The

pathological reports on the sixty-three cases of excision showed chronic inflammation in fifty-six cases. X-ray studies were made on fifty-six of these cases, but a cholecystography was done on only twelve of the fifty-six. In twenty of the cases flat plate and G. I. X-ray reports were negative for any pathology, but laboratory reports showed inflammation or stones.

## THE POSSIBLE RELATIONSHIP BETWEEN CONVULSIONS IN EARLY LIFE AND EPILEPSY\*

By WILLIAM T. SHANAHAN, M.D., SONYEA, N. Y.

Superintendent, Craig Colony

OBSERVERS have long sought to determine as to the relationship, if any, between convulsions in infancy and early childhood, convulsionosis, with epilepsy, convulsive disorders, in the adolescent or adult. If we accept what many contend, that epilepsy is rarely hereditary, we might expect that many convulsions are due to some fundamental enduring disturbance of the individual occurring in early life. Predisposing or precipitating factors to be considered are neuropathic heredity, parental syphilis and alcoholism damaging germ plasma, fetal maldevelopment, birth or subsequent head trauma, encephalitis and meningitis from infections such as scarlet fever, measles, etc., or mechanically as in pertussis, long continued metabolic disturbances, such as rickets, endocrine disorders and psychogenic abnormalities.

What constitutes an epilepsy? On what can a reasonable prognosis be based? While certain theories are attractively plausible, still they are but theories and must long remain as such. Our knowledge of the actual biochemistry of the central nervous system, as well as other vital organs and tissues, is meagre. What do we know regarding life processes of essential nerve cells? It has been advanced that epilepsy may be the result of a primary neuronc degeneration.

To show opinions of seventy years ago, I quote from West<sup>1</sup>, who mentions convulsions consequent to large loss of blood, that the brain in infancy is much more exposed to disorder than that of an adult, owing to the far wider variety of influences to which it is susceptible, and the frequency of convulsions in the young and the great variety of circumstances under which they occur, making it difficult to interpret their meaning. The cranium of the adult is a complete bony case and the firm substance of the brain affords a comparatively unyielding support to the vessels by which it is nourished. It is not so in

infants and the same causes which expose the brain to be overfilled with blood render it possible to be drained of blood more completely than in the adult. Convulsions take place in infancy not as result of any disease but simply in consequence of this anatomical peculiarity. West says it would not be right to attribute convulsions that sometimes occur at commencement of eruptive fevers entirely to derangement of the cerebral circulation, for something is probably due to changes in the blood itself. "The period of teething, like that of puberty constitutes one of the great epochs of life where changes are going on in the whole organism." "Convulsions in early life are unusual after the completion of dentition and warrant more serious apprehension in children of three or four years old than in infants of a year or eighteen months." "There seems to be a decided relation between the liability to convulsions in early infancy and development of epilepsy in subsequent childhood." He mentions that alleged causes of fits are not always the real ones, and stresses nodding spasms and petit mal in childhood continuing into a later epilepsy, mentioning momentary vertiges and attacks of apparently causeless alarm accompanied by incoherent talking. "The prospect of epileptic seizures ceasing at puberty is a very groundless one." "The severity of fits is of less importance in the prognosis of epilepsy than frequency of their occurrence. The oftener they occur, even in a mild form, the less is the prospect of their cessation."

Writers on dissimilar heredity in epilepsy give percentages varying from 1 to 87 per cent, differences so great as not to be satisfactorily explained except upon exceedingly incomplete data and including disturbances with little or no relation to nervous or mental disorders, thus much of what has been written regarding heredity in epilepsy and related conditions is without value from present day standards. Early writers discountenanced the admission of other nervous affections in ancestors as hereditary predisposing causes of epilepsy. In

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N. Y., May 11, 1927.

regard to similar heredity, some writers have made positive diagnoses of epilepsy in ancestors on very unsubstantial grounds. How can one be sure of such diagnoses when it is often difficult to make a diagnosis in the living, even under fairly close supervision? Such extravagant assertions make one question seriously the value of the findings recorded. Others contend that every convulsion in the human must be epileptic.

The Mendelian laws are difficult to apply in the complex organism of the human family, especially in regard to disease. There has been a steady tendency in recent years to lay more stress on environmental factors as compared with hereditary influences.

Myerson<sup>2</sup> explains that the conception of heredity as a cause of epilepsy is gradually disappearing and that accurate clinical and biochemical studies show that the disorder is one of organic type.

Seguin<sup>3</sup> said "Every spasm is not epileptic, its form, distribution and especially its evolution and association must be considered. He cautions against accepting coincidental factors as causative of the convulsion. After three years of age, look with doubt upon such alleged causative factors as gastro-intestinal disturbances, worms, etc.

In Binswanger's<sup>4</sup> opinion, convulsions in the first few weeks of life indicate life-incapability and later in infancy they are due to the physiological disposition to convulsions, owing to the incomplete development of the central nervous system. He believed infantile eclampsia may be the prelude as well as the disposing cause of epilepsy.

Echverria<sup>5</sup> mentions epilepsy as a name synonymous with convulsions, indiscriminately employed by ancient and modern medical writers to indicate definite spasmodic affections and that no other malady exhibiting a wider range in etiological conditions accounts for the confusing application of the term. He further states, there is scarcely a disease in which epileptiform convulsions might not occur. According to Russell Reynolds<sup>6</sup> "the immediate or approximate cause of convulsions is a change in the nutrition or interstitial processes of the nervous centers." In what essential does this explanation differ from that of our own time?

Watson Carter<sup>7</sup> mentioned "Not every person having epileptoid or epileptiform attacks could be called epileptic, that a convulsion is only a symptom and not even essential, that one cannot preclude the possibility of having to do in one of these cases with epilepsy beginning in early life, a question which can only be determined by the continuance of the convulsions."

It has been alleged that in families of epileptics a larger proportion of adult members of such families have had infantile convulsions than did the epileptics in such families. Examples of this, to me, rare occurrence are the following.

A P, ninth in family of ten children, eight boys and two girls. All natural born, breast fed and strong. During early infancy every boy except the patient had convulsions. The first and sixth, girls, never had convulsions. Of the boys, the second died at 21 years of pneumonia, he had convulsions at irregular intervals during his life, married and has one healthy child. The third had convulsions in infancy, then a remission until eight years when a single convulsion occurred, with no recurrence. The fourth had convulsions in infancy, and a single convulsion at four years, without recurrence. The fifth had no convulsions after six months of age. The seventh, a twin, had convulsions during dentition without recurrence later. The eighth, the other twin, had convulsions in infancy and at the age of eleven months had a severe convulsion complicating a fatal broncho-pneumonia. The ninth is the patient. The tenth had convulsions in infancy without recurrence. The patient was the only one of the sons free from seizures during infancy. At five years he fell several feet, suffering a deep scalp wound, no apparent ill results immediately following. Two years later, while pulling weeds in a field on a farm he, without apparent warning, had a severe seizure, such having recurred at irregular intervals. Discharged from Colony in 1920 as recovered, no seizures having occurred in over two years.

H N, aged 32 years. Born at full term, natural delivery, weighed twelve pounds. Began to walk at 13 months, showed evidences of rickets. When  $3\frac{1}{2}$  years old, fell down stairs and was unconscious for nine hours. A month later had a convulsion. At about seven years of age attacks ceased for nine months. Then his oldest brother dipped him in the river, scaring the child. The following day he had a convulsion. All of the patient's brothers and sisters had convulsions in early life, six dying before one year of age. The three surviving, besides the patient, are adults and have had no recurrence of convulsions since infancy. Two are married and have healthy children.

It has also been stated that epileptics no more frequently give a history of convulsions in infancy than do non-epileptics.

Riddoch<sup>8</sup> states that convulsions in infancy are about twice as frequent in families with hereditary history of epilepsy as compared with those without such history, and that in

epileptic families there are a greater proportion of epileptics among the first-born than those born later In 2,036 consecutive cases at Craig Colony the order of birth was as follows (231 cases being entirely unknown)

infants who survive, considerable damage may have occurred to the brain, insufficient to cause death, but enough to interfere with normal development and to result in neurological symptoms, many of which would be con-

It is difficult to ascertain as to how many in the general population are first born, second born, etc, so as to permit of comparison

Wilson<sup>9</sup> says "Convulsions can be brought about experimentally in animals anatomically and physiologically normal, i e, a fit may be a discharge of accumulated nervous energy in a healthy neuro-mechanism Some fits are clearly cortical, some at obviously lower levels We do not know the conditions under which the accumulated nervous energy is discharged.

Stewart<sup>10</sup> believes there is an infinite variety of causes of epilepsy acting in persons otherwise normal and healthy

Peterman<sup>11</sup> states convulsions in new-born infants are probably organic, those occurring during the first few months of life are usually due to congenital malformation of brain or skull, those between eight months and three years are functional, due to spasmophilia

Sharpe and Ulrich<sup>12</sup> report that 15 to 20% of normal children show blood in the cerebro-spinal fluid, indicating hemorrhage, usually subarachnoid They believe that many other causes of brain injury do not show blood in the spinal fluid, especially if lesions are intracerebral This might explain a good deal of sporadic feeble-mindedness and epilepsy

In a study of 1,673 cases of still births and neonatal deaths, Holland and Clayton<sup>13</sup> show that 25% are due to intracranial injuries, and also that 33% of all cases of version showed intracranial lesions 465 of the total deaths were due to the complications of labor These findings suggest that in a large number of

vulsions, perhaps continuing into epilepsy

Several are of the opinion that various paralyses, convulsions, etc, observed in young infants are not to be attributed to meningeal hemorrhage at birth but to various pathological processes of intrauterine origin

Many call attention to the fact that serious brain injuries occur not only in pathological labors and those artificially terminated, but in many so-called normal labors

Schwartz and Frink<sup>14</sup> refer to microscopic bleeding in the brain in premature babies and that asphyxia is of secondary importance as cause of such hemorrhage

Collin<sup>15</sup> says the well-known tendency to convulsive states in infancy is due to the structure of the brain, to disturbance of calcium concentration, and to insufficient development of suprarenals and parathyroids Convulsions due to these factors may be considered as benign as distinguished from the manifestations of epilepsy Their symptomatology can be explained without participation of the cortex They are clonic and bilateral without stertor, frequently precipitated by fever, not coming on during sleep, and disappearing as the child grows older On the other hand convulsions starting unilaterally, tonic in character, producing asphyxia, apyretic and occurring in sleep or immediately after waking are epileptic in nature

For some unknown reason, certain individuals present recurring epileptiform attacks and other individuals with apparent defects in makeup which should provoke such attacks,

are free from them. We know that in adults, perhaps because of a fully developed nervous system, one observes convulsions recurring in only a small number of individuals who sustain serious head trauma, e.g., soldiers.

Encephalitis complicating any infectious disease or the result of direct infection of the central nervous system, not sufficiently severe to cause death, may result later in mental impairment, convulsions, etc. Recurring oedema of the brain as a cause of convulsions has long been recognized. The appearance of the brain in a case dying from a severe influenza infection suggests the possibility of what might occur in a patient recovering from such a severe infection.

Apparently as result of certain changes in the body chemistry associated with acute infectious diseases, epilepsy may ensue or if already existing may be aggravated, or on the other hand, such infection may cause abeyance of such seizures for a considerable period of years, or even in a few cases permanently. Some allege acidosis, others alkalosis may cause convulsions.

Again writers have suggested that some convulsions in early life are due to anaphylaxis or a similar process set up by ingested cows milk, white of egg, oatmeal or other common foods of young children.

Hempelmann<sup>16</sup> states acute throat infections, such as tonsillitis, have more frequently caused convulsions than gastro-intestinal upset. He mentions the well-known fact that once the child reaches the age when febrile convulsions are ordinarily less common, it takes an unusual occurrence to precipitate them, e.g., onset of meningitis, severe scarlet fever, toxic pneumonia, etc. In 250 cases of spastic paralyses, he found the percentage of epileptics very small.

I have seen diphtheria, tonsillitis and mumps cause marked nervous reactions. What virulent poisons are manufactured within the body by germs and carried to the brain to act as irritants provoking convulsive phenomena? High fever, although present, may not be the cause of the seizure.

Hunt<sup>17</sup> considers epilepsy as an inhibitory disorder of the brain and that children are so prone to convulsive attacks largely because the inhibitory mechanism is so underdeveloped. He also mentions that acute infections often show a tendency to become localized in this or that portion of the nervous system, the explanation for which is far from satisfactory in the present state of our knowledge. It would appear as if strains of some organisms may have special selective affinities for certain tissues of the nervous system, thus producing special clinical types or reactions. Theoretically, exhaustion or biological in-

feriority of parts of the nervous system may render it more susceptible to the deleterious influences of toxic products.

Dandy<sup>18</sup> concludes that the motor cortex once injured, the threshold at which convulsions appear is lowered, and that injuries to other parts of the brain may lower such threshold to a lesser degree. He holds that the motor cortex is alone responsible for the occurrence of clonic convulsions, although the attack may not originate there.

Syz<sup>19</sup> states the well known fact that asphyxia, especially when produced by interruption of the blood supply to the brain, produces convulsions. Lack of oxygen or material increase of carbon dioxide causes hyperexcitability of the nervous system and convulsions.

Heuyer<sup>20</sup> believes convulsions in infants are to be considered as identical to epilepsy in adults, being produced by the same factors. He recommends prolonged anti-syphilitic treatment even when clinical and serological examinations are negative. It would seem as if this author does not accept the general opinion that convulsive reactions are in but a limited number of cases due to congenital syphilis.

Vogt<sup>21</sup> believes hereditary syphilis may cause thinning of cerebral blood vessels, making them more easily ruptured and interfere with tissue development, thus more easily producing epilepsy and mental defect.

Patrick and Levy<sup>22</sup> in referring to convulsions and their recurrence, say that the presence of such convulsions, per se, multiplies the individual's ordinary chances of epilepsy by at least five, and that there is no definite interval of safety beyond which epilepsy will not occur.

Bassoe<sup>23</sup> says, "It is surprising how little real definite information is to be had when one thinks of the many millions of epileptics that have lived and the tens of millions of children having convulsions, yet statements are based on general impressions and not on available data."

The point has often been brought out that the contact of the obstetrician and pediatrician with convulsive cases is comparatively short, so that their knowledge of subsequent events in the life of the child is limited. On the other hand, neurologists often have difficulty in determining, in the adult, what actually happened during early childhood.

Many cases of headache, alleged fainting spells, and certain psychic and temperamental trends are closely related to epilepsy. Rosanoff believes that epileptoid tendencies are widely spread in the population, being perhaps almost universal but latent under ordinary conditions.

Clark<sup>24</sup> believes convulsions in children and epilepsy in later life have no essential relationship, that only in predetermined cases are convulsions in infancy of any moment, that epilepsy is due to an essential makeup, entailing poor adaptation to reality, the handicapped individual deteriorating through failures and disappointments, so that he is turned back on himself, and that there may be organic reasons for such reaction

Wiersma<sup>25</sup> says that fundamental nature of epilepsy is inherent failure to adequately assimilate impressions from the outside world, and holds that convulsions and mental characteristics associated with epilepsy are secondary and dependent phenomena. He concludes that absent-mindedness represents a transition between the normal and the epileptic

To seek viewpoints on the subject in hand, I addressed over eighty pediatricians and neurologists, obtaining replies from but 50%. I mentioned that it was generally accepted that convulsions are common in young children during acute gastro-intestinal disorders and at the onset of acute infectious diseases, and it was also rather generally conceded that infants sustaining severe head injury during birth, if they survive, will ordinarily be epileptic or defective, or both. Summarizing the replies, I can but say that the information obtained does not make more exact our knowledge on the subject. A number replied that they had no definite findings to offer, one well-known pediatrician saying that convulsions were so common they were not recorded. Others replied that convulsions in early life were uncommon, while some asserted that as high as 25 to 50% of all infants and young children present convulsions

The commonly obtained history of trauma in infancy is difficult to evaluate as to its bearing, if any, on a later epilepsy. It is often not especially severe, nor does it differ in any respect from trauma received by practically all young children

Replies from a considerable number were to the effect there was little or no definite relationship between convulsions in early life and epilepsy, while on the contrary, a few replied that the majority of epileptics give a history of convulsions in childhood and that 25% or more having convulsions in infancy have recurrence later

In a series of 1,000 patients at Craig Colony, 32.6% had convulsions in early life, of these 238, or 23.8%, had convulsions first appear in infancy or early childhood, before four years, and continue into later life. 88 cases, or 8.8%, had convulsions in infancy with remission, 20 for less than five years, 28, from five to ten years, 24, ten to fifteen years, 14, fifteen

years and over. In a number of cases the supposed exciting cause for the recurrence is not mentioned. In others, various factors are alleged, e.g., school attendance, puberty, intercurrent illness, indigestion, etc. In these same cases the alleged exciting cause for the first convulsion was no assigned cause, 44, dentition, 22, at or immediately after birth, 10, infectious diseases, 4, fall, 3, worms, 2, indigestion, 1. In a number where dentition is mentioned, it no doubt was only concomitant

How many children, potential epileptics, die before the diagnosis is made, or before reaching an age when a diagnosis might be possible?

In another series of 1,000 cases, 31.6% had convulsions in early life, of these 200, or 20%, had convulsions continue uninterruptedly into later life, 116, or 11.5%, had remissions for varying periods: 8, four years or less, 39, five to ten years, 40, ten to fifteen years, 29, fifteen years and over. The assigned cause of the original convulsions in this series was as follows: 13, none, dentition, 63, indigestion, 11, birth or directly after, 10, fall, 8, infectious diseases, 3, worms, 3, fright, 1

Schlapp<sup>26</sup> found in 1365 epileptics that 29% had convulsions during infancy. Thom reports 515 of patients at the Massachusetts Hospital for Epileptics as having the first convulsion prior to the fourth year

Some convulsions in children are due to acute nephritis. Any condition causing increased intracranial tension may result in convulsive phenomena. Excessive water intake may produce convulsions. It is conceded that mechanisms involved in the production of convulsions are in a considerable number circulatory disturbances within the skull, either vascular spasms, venous congestion or increased blood pressure from whatever cause. As to just how some of these conditions are brought about is not known

Scott and Usher<sup>27</sup> report 21 cases of infantile tetany in all of whom generalized convulsions were present

Grover F. Power<sup>28</sup> states that the nervous complications of pertussis generally attributed to asphyxia, cerebral edema or congestion, cerebral hemorrhage, encephalitis or meningitis, the resulting outstanding symptom of all of which is convulsions, are due to tetany and not to the anatomic injuries aforesaid.

In the literature in recent years, there have been many references to convulsive attacks after hyper-ventilation of the lungs. Does prolonged crying in young children produce an effect similar to hyperpnoea and so cause convulsions? What about efforts at respiration made by the infant in the latter stages of protracted labor?

Starkey<sup>29</sup> believes that spasms of the un-

striped muscles are responsible for circulatory changes involving basal ganglia, which in turn, account for epilepsy and similar disorders

Epstein<sup>80</sup> states "spasms in children have as their etiology a physiological and not an anatomical pathology. The relation of spasms in children to the neuroses in later life seem to be in many cases a close one"

Holt<sup>81</sup> and others have never seen convulsions which could fairly be attributed to dentition, although such may occur in rachitic children. They further state that worms as a cause of epilepsy is extremely rare. No matter what the apparent or relating cause of convulsions during infancy, there is no doubt but what constant repetition may establish the convulsive habit. As Kerley<sup>82</sup> well states, "the second seizure is more easily produced than the first, and the third more easily than the second," that convulsions should never be lightly regarded as they may be serious in their immediate as well as their remote possibilities. One convulsion may produce cerebral hemorrhage

Several observers believe that in a number of infants showing convulsions immediately after birth many had eclamptic or uraemic mothers

Rickets is assigned as a predisposing cause for many convulsions in early life, but spasmodophilia is credited as the cause of the major proportion of convulsions occurring under three years. A spasmophilic may also later prove to be epileptic, a long period of observation being necessary to differentiate. As a point of differential diagnosis, reference is made to the seasonal occurrence of spasmodiphilia and that in the latter there is also evidence of disturbance of nutrition as contrasted with epilepsy

Thom<sup>83</sup> believes that "if infantile convulsions associated with rickets, gastro-intestinal upset, acute infections, etc., were looked upon more seriously and greater effort made to prevent their occurrence during early life, much epilepsy and mental deficiency might be prevented". He quotes a study by the Children's Bureau of New Haven, Conn., showing the incidence of convulsions among 1,101 untreated cases of rickets as 47%, while in 350 treated cases convulsions occurred in 15%

While teething as an explanation of spasms is too often a cloak for ignorance, still dentition is physiological and it is not incapable of disturbing health, according to Still<sup>84</sup>. He also mentions that it is not necessarily the use of forceps that causes brain damage, but the condition necessitating the use of forceps, as being likely to result in more or less asphyxia and consequent brain damage. He refers to unexplained attacks of giddiness as being so

to speak, the fringe of epilepsy. He describes so-called "inward convulsions" in which the child screams, becomes livid about the mouth, perhaps turns its eyes upward, at the same time thumbs to the palms. In another case there is momentary twitching, perhaps extremely fine, of the forearm or leg, or perhaps only the fingers, with in turn loss of consciousness. In another there may be a sudden start of the whole body. These symptoms, seemingly trivial, are just as truly convulsions as major attacks, standing in the same relation to such as *petit mal* does to major epilepsy. He believes a mere bout of crying may end in spasmodic closure of the glottis with cyanosis, unconsciousness and a general convulsion. Fully 50% of permanent infantile hemiplegia begin with convulsions although perhaps only a very small proportion of these have been caused by the convulsion. Still believes that out of the enormous number of infants who have convulsions an extremely small proportion become epileptic, at any rate before the age of puberty. He stresses the time of the first, also perhaps the second, dentition and puberty as being critical periods for children of neuropathic tendencies

Muskens<sup>85</sup> believes occasional seizures occurring in childhood, e.g., at the onset of febrile disorders, are defensive in nature, being the method of discharge of a toxin injurious to the organism. He believes that too little attention is given to the significance of myoclonic movements found in young normal children, e.g., if a young child is asleep a sudden noise may produce glottic spasm. He does not consider the holding of breath by emotional children as a sign analogous to the occurrence of a convulsion. In a series of 2,000 epileptics observed by Muskens, 12.6% gave a history of convulsive phenomena occurring in infancy

Types of *petit mal*, or mild seizures, often overlooked, are staring, making peculiar grimaces, sounds, etc., enuresis especially during day time, various jerks, hesitations in speech, movements, responses, etc., faints, complaints of peculiar sensation in abdomen or head, etc., vertigo, petechial hemorrhage of the skin, eyes, screaming spells, flashes, sudden dilation of the pupils, saying or doing something odd, child seems to lose himself, swallowing movements, drooling, fumbling, fussing, all the foregoing stereotyped in the particular individual

Watch out for the so-called masked epilepsy, e.g., sudden transitory loss of speech, sudden dreaminess, sleepiness, giddiness, alleged fainting attacks, etc.

The alleged excess of cases of left-handedness in families of epileptics is not generally accepted

In 7,000 admissions to the Craig Colony, the age at onset in 28% was before five years of age. In 1,500 admissions of all ages, 12% gave a history of cerebropathies complicating infections, and 8% of trauma at birth or shortly thereafter.

Patrick and Levy remind us of the uncertainty as to what constitutes epilepsy, polymorphism of the disorder and the fact that the diagnosis is ordinarily largely made from statements of the patient and others. They mention thirty conditions to be differentiated from epilepsy.

As examples of typical histories of those under discussion, I would cite the following:

K K, aged 31 years. Father living and in good health, temperate in habits. Mother died at 52 years, cause unknown. Said to have been very quick tempered, otherwise no history in family of nervous or mental disorders. Patient born at full term, short labor, instrumental delivery. Weighed ten pounds at birth, said to have a wound on side of head from instruments. No prenatal influences mentioned. Had convulsions immediately following birth, but was not paralyzed. Nursed by mother. Dentition began at 8 months. No unusual symptoms. Walked at 15 months and talked at 2 years. Began school at 6 years and reached second year high school at 13 years. Had measles and whooping cough at unknown ages. First epileptic seizure alleged to have occurred at 13 years, during sleep, the second seizure occurring an hour later.

C W, aged 28 years. Father excessively alcoholic. Mother's oldest sister had convulsions, perhaps epileptic, died at 36 years. Mother's brother insane. One of fraternity died at 18 years of convulsions. Mother had fainting spells about 2 years before patient was born. Patient's birth instrumental, duration of labor three days. Was unusually large child if weight given is accurate, 11 pounds. Said to have been a blue baby. Shortly after birth patient had fainting spells, cried a great deal until 3 months of age, was always excitable and childish in his manner. Began school at 5 years and reached 6th grade at 11 years. Had typhoid fever at 20 years, during convalescence from which he had a severe convulsion, another occurring in 3 days.

O O, aged 11 years. Paternal grandfather died at 50 years of cerebral hemorrhage. Parents of patient living and well. During year previous to birth of patient mother had fears of various kinds. Patient's birth and early infancy negative. Nursed by mother. Dentition began at six months. Walked at 18 months. Considerable delay in talking, apparently slow to develop. Convulsions first appeared at 18 months, attributed to intestinal irritation and worms. Seizures continued.

L B, aged 12 years. Father living and in good health, aged 50 years. Mother is living, aged 45 years, said to be in "weak and run down condition." Parents were second cousins. Paternal grandfather died at 55 years from unknown cause. Grandmother died at 70 years from unknown cause. Maternal grandfather is living, aged 70 years, grandmother is living, aged 60 years. One sister died at 4 years, of epilepsy. All others are living. Birth was premature, being two weeks before the expected time. Mother's condition was very weak at the time, being exhausted from frequent previous births. Delivery was natural, baby weighed 12 pounds, was considered strong. Patient not injured in any manner during delivery. Said to have had convulsions immediately after birth, accompanied by high fever. No paralysis noted. Was fed artificially and was not subject to indigestion or prolonged spells of crying. Teething began at 1 year, said to have had violent convulsions at this time. Walked and talked at 2 years. Experienced no difficulty in learning either. Said that his mind developed naturally during infancy and early childhood. First attended school at 6 years, reaching fifth grade at 11 years. No history of injury that might have a bearing on his epilepsy. Had measles at unknown age. Onset of epilepsy is given at 8 years, said to have been brought about by fright.

D F, aged 22 years. Father living, aged 52 years, in good health. Mother died at 48 years of endocarditis and chronic embolism. Father's father and mother both living, aged 75 and 73 respectively. Mother's father and mother both died of pneumonia, aged 67 and 52 respectively. Patient second in line of birth of 5 girls, of whom 1 girl died at 2 months of marasmus. Mother had no miscarriages. A first cousin had dementia praecox. Born at full term, natural delivery, weighed 6½ pounds at birth and was strong. No adverse prenatal influences given. Nursed by mother. Had convulsions when 5 months old. Dentition began at 6 months. Began to walk and talk at 14 months. First attended school at 6 years, and reached second year high school, at 15 years. Had measles at 4 years. Alleged onset of epilepsy at 12 years. Puberty at 15 years.

J C, aged 18 years. Patient first of six children, three boys and three girls. One sister had a convulsion at 2½ years, none since and is now 9 years old. One brother had 1 convulsion at 2 years, none since, and is now 6 years old. Otherwise the family history is negative as to nervous and mental diseases. Patient did not have rickets. First attended school at 4½ years and made good progress, graduating from grammar school at 13 years, and then attending continuation school for 2

years Has received no accident or injury that might be of etiological importance Had measles and whooping cough at 7 years and diphtheria at 13 years, the latter disease being very severe and complicated by nephritis One month following this illness, he had first attack of epilepsy, which was extremely severe

### CONCLUSIONS

There is, then, wide difference of opinion as to the significance of convulsions occurring during infancy and early childhood, some maintaining such reactions are of only passing moment, others insisting they may portend a later epilepsy As in other situations in the fields of diagnosis and prognosis, one must be cautious in expressing a definite or final opinion

Many hold that all convulsive attacks, especially occurring singly and during infancy, without apparent adequate cause, are essentially epileptic, their continuance in after life depending on predisposition and treatment Even in a previously healthy infant with good heredity a convulsion from any cause is a serious symptom as it may be complicated by hemorrhage of the brain, permanent damage ensue, and convulsions recur The first convulsion itself may not be epileptic but may thus cause an epilepsy

The child who has convulsive attacks, be they so-called "worm fits," "teething fits," or what not, may have these disappear for a period, but the convulsive tendency has been established and simply remains to be again brought to light at a later period

The forming of the convulsive habit may be by methods similar to forming any habit, the nervous system responding more easily to certain stimuli

Be extremely careful in pronouncing obscure nervous symptoms as of no consequence, especially if recurrent within comparatively short intervals Such children should be closely observed over an extended period, the general care given being the same as if epilepsy had been definitely diagnosed

Petit mal is overlooked oft times, being called "peculiar spells" If present with convulsions, epilepsy must be considered most seriously

Unless there is a family history of epilepsy or of definite brain injury at birth or a subsequent encephalitis, be cautious in making a diagnosis of epilepsy in an otherwise normal young child who has a few convulsions Many children who might be expected to have epilepsy do not have it One writer truly cautions "Avoid casting the stigma of epilepsy on a child"

As epileptiform reactions occur in so many disorders the diagnosis of epilepsy should

only be made by exclusion after thorough study and observation of the particular individual. Two convulsive disorders may be concomitant, e.g., epilepsy and hysteria Remember it is the recurrence of seizures over an extended period that constitutes what we call epilepsy Any person may at some time of life have some sort of an epileptiform reaction In fact, some writers say we are all epileptics When one considers the complicated and intricate structure of the entire nervous system, as well as the circulatory, digestive and other vital systems with their inter-relationship, one is surprised that there are not more reactions epileptiform in nature The brain itself may be normal, but its functional response be perverted by toxins of various sorts and from numerous sources

Compare sleep starts with myoclonic jerks, absent-mindedness and day dreams with petit mal, and one appreciates the lack of sharp definition between normal and perverted function of the living human mechanism Consider the psychic processes and their effect on function of the systems before mentioned

Time will not permit describing narcolepsy, pyknolepsy and other rarer disorders resembling epilepsy Epilepsy can be diagnosed with more reasonable certainty at an early age if there is an evident organic basis present, e.g., cerebral palsy, mental impairment resulting from encephalitis associated with acute infectious diseases, etc Epilepsy, however, is not a species of mental defect, although such may also be present

Any alleged increase in the number of epileptics in a community is probably more apparent than real, statistics being so incomplete that they must be cautiously accepted and remembering the interpretation of the term epilepsy and what it includes differs widely

## PIGEON HOLE DERMATOLOGY\*

By WALTER JAMES HIGHMAN, M D, NEW YORK, N Y

A PATIENT with dermatitis herpetiformis consults a specialist, who mentally lists the alleged causes of the disease—general infection, focal infection, a metabolic disturbance, misbehavior of the ductless glands, anaphylaxis. Blood cultures and blood counts are made, the teeth are subjected to X-ray examination, the tonsils and sinuses are investigated, the urine and blood are chemically analyzed both quantitatively and qualitatively, sensitization tests are performed, the basal metabolism is determined. Nothing abnormal is found. But the patient has dermatitis herpetiformis. The gastric contents and feces are examined. No clue is furnished. Roentgenographs of the chest and abdomen are ordered. The explanation remains elusive. Root abscesses of two molars are discovered. The offenders are extracted. The root abscesses have automatically vanished, not so the dermatosis. This story might be duplicated as to pemphigus, psoriasis, exfoliative dermatitis, prurigo, some cases of eczema.

Hebra himself, were he among us today, could as little cope with the situation as the greenest tyro in a skin clinic. He would share our chagrin, our sense of limitation. We among dermatologists who are no longer very young, and not yet old, still hope that before the curtain descends upon our view of the dermatologic—shall I say tragedy, or merely comedy—the plot will in part have revealed itself. We look to our younger colleagues to engender for their own eyes a clearer stage than we shall ever behold.

May a few reflections be here recorded, born of the experiences and disappointments of a score of years devoted to dermatology? May a

tentative outline be sketched of what may carry the riddles of today somewhat nearer a solution? If the writer more closely approximated the ideal dermatologist to be pictured below, perhaps he might himself attempt to achieve some of the solutions, instead of merely draughting a scenario. A scenario, indeed, that may have no real soundness, no creditable force. Such as it is, this paper is dedicated to those who may accord it a sympathetic ear, and to those who, a generation hence, will not too ungenerously ridicule the fancies and hopes of a writer of today.

During the 19th century dermatology was largely an exercise in optical acumen. It is true that in France many dermatoses were ascribed to "dartres" and in England to the gouty diathesis, but this was merely speculative medicine and about as sound as the humoral pathology of the ancients. Essentially there was no dermatology during the past century except clinical dermatology, until the researches of Virchow, Pasteur, Koch and Von Behring began to influence all contemporaneous medicine. Up to that time dermatologists did with dermatoses what little boys do with butterflies—they caught them and pinned them to the wall. They established a habit of catching and pinning, and this habit, like the theme of a fugue, appears to haunt with its insistence all our thought. The catching and pinning was a necessary episode in the development of dermatology, as necessary, no doubt, as the alphabet or the rules of rhetoric or harmony and counterpoint in their various spheres. The catching and pinning constitute clinical dermatology.

Clinical dermatology in its proper place is not to be belittled. It is the essence of dermatology. The naming of dermatoses, the attempt to classi-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 11 1927

fy them, to arrange their relationships, is the soul of the science. But when the dockets, the pigeon holes are apotheosized it becomes wholesome to court the joy and risk of apostasy as to a ritual that obscures its own object. The spirit reigning over medicine or any branch of medicine (and this, curious as it may seem to some deans and faculties, includes dermatology), is understanding diseases as processes and not as evil spirits to be exorcised. As soon as a disease is understood, its designation ceases to be a handicap. Thus today it does little harm to speak of *lupus vulgaris*. This imbecile designation cannot conceal the fact that it is tuberculosis of the skin. The equally idiotic term *lupus erythematosus* persists. The bias that since one *lupus* is tuberculous the other must in some way also be, shows how names shunt thought. *Lupus erythematosus* may be tuberculous, but suppose it should prove not to be! So far there is little evidence that it is. A generation ago Unna suggested the name *ulerythema centrifugum* for this condition, a perfect example of perfect nomenclature. Who on earth can explain the reluctance of dermatologists to accept it? A peep into a pigeon hole might disclose the answer.

A peep into other pigeon holes might uncover why terms like *erythroderma* are preferred to *dermatitis exfoliativa*, *prurigo* to *papular urticaria*, *herpes zoster* to *zoster*. Many more could be added. The reason is that the terms are ready labels. They do not convey the idea of processes to the mind, but of pictures, and when one dermatologist utters a word from this caballa, another can readily conjure up the portrait. For example, Boeck readapted the term *sarcoid* for the disease named after him. In a posthumously published paper he retracted the term and suggested "miliary lupoid." Faulty enough, but better than the vacuous original designation, yet his last suggestion has been ignored. Probably it has not even been widely heard of. This should not arouse great astonishment, for in our country it is not even understood how to pronounce Boeck's name, although the correct pronunciation would fall easier to American lips than the way we say it when we think we say it correctly. This is a bagatelle, but of a certain significance, for when we ignore an author's attitude toward the naming of a disease he has described, when we ignore even predigested thought, how can we hope that we shall think for ourselves about other diseases?

It is not intended to give the impression that this type of slovenliness of thought is peculiarly American. Aside from the work of Jadassohn, Bruno Bloch, perhaps some of Kreibich's, Rost's recent textbook and some of the investigations on *tinea* by Plato, Kauffmann-Wolff and, again, Bruno Bloch, and as a classifier, Sabouraud, the bulk of continental dermatology in the last generation has been more of the clinical variety, the

name calling type, even than ours. In England Norman Walker, and in the United States Schamberg, Engman, Pusey, the late James Johnson and Frederick Harris, Stokes, Weidman, Wile, Jeffrey Michael, have all engaged themselves largely with dermatology in its wider aspects, both as to causation and treatment. Several other names might be added to this list and their omission implies no disrespect, but those enumerated suffice as examples. These writers, or triple their number, are only a handful among American dermatologists, as a visit to almost any of our great dispensaries or to any of our great clinical gatherings will reveal.

Let us spend a moment at a clinic. We all have done so as participants. This is how one looked to an outsider whose impressions are restated in the third person. A patient, apparently sworn to silence, sat opposite an equally inarticulate physician—a sphinx with an eagle's eye. After an appreciable period the sphinx turned oracle and unburdened himself of the name of a skin disease. Thereupon the currents of inductive questioning were turned on, and a history crystallized itself about, and supported the diagnosis. Science now stalked in. A Wassermann test and biopsy were ordained, and rhubarb and soda mixture, calamine lotion or the Roentgen ray invoked. The ritual seemed complete. To sum up, the diagnosis preceded the history, preceded the report of laboratory investigations, and treatment was based upon a name. If this is logical, it is logic in reverse speed. This is only a newer way of saying that the cart was put before the horse. I can see no reason why modern dermatology should not be based on principles of thought that were known to Euclid, unless it be that the sport of snap diagnosis has become a habit. Pigeon hole dermatology!

The same fallacy inspires clinical sessions. Diseases are named. Papules and pustules rather than principles and problems burgeon into oratory. An exchange of verbal amenities is the order of the day—verbal amenities about the still unknown. For example, if a border-line case is shown that may be *mycosis* or *parapsoriasis*, the chairman must use his gavel in an almost corporeal onslaught on the speakers to end the discussion in time for dinner or the train or a golf match. If a case of leukemia is presented with complete supporting data, someone arises to congratulate the presenter on his complete presentation. It seems as though it were always possible to fulminate more about what is unknown than to elaborate and reason about the known. Speculative cases produce torrents of words. Studied cases produce silence, or at the best, a grudging compliment. Pigeon hole dermatology!

One more short excursion before we return to the main path of this paper. Now and then when discussion does transcend the level of nomenclature and wings the rare ether of etiology, we hear

this sort of thing "Herpes zoster is due to focal infection, at least insofar as my experience goes" What Dr So-and-So's experience is, where the focal infection is, what the pathogenic parasites are, are not mentioned. When he is asked how a self-limited disease, usually conferring permanent immunity, can be due to a focal infection, he has no rebuttal but he does not retract. And focal infection has been blamed for erythema multiforme exudativum, for zoster, for simple herpes, for lupus erythematosus, pemphigus, for eczema. I desist. Why name all the dermatoses there are? Dr Thus-and-So states that pityriasis rosea is, in his experience, strikingly often associated with, and hence due to, bad tonsils, or diseased tonsils, probably he said diseased tonsils, for who would wantonly call a defenseless tonsil "bad?" He does not mention in what ratio he sees such cases in people with affected and unaffected tonsils, or whether this differs from the ratio of such tonsils in people without pityriasis rosea, or whether a similar state of tonsillar evil exists with reference to other common dermatoses, or whether, indeed, having no tonsils at all safeguards people from pityriasis rosea. As a matter of fact tonsils have been caught in flagrante in all the diseases above mentioned and in many not mentioned, particularly in relation to focal infections, and held culpable with about the same degree of logic. Thus, zoster—focal infection, pityriasis rosea—tonsils, urticaria—milk, eggs, strawberries or shellfish (bivalves and crustacea, the crustacea not bearing shells, and none being fish), eczema, psoriasis—uric acid, seborrhoea—carbohydrate chemical disturbances, acne—sweets and constipation (an easy evasion of real thought upon the disturbances of puberty). Why go on? Thin ice etiology! Thin ice etiologists! Pigeon hole dermatology!

It is easy to be a destructive critic. It is unfair to be one without trying to offer at least the egg of a phoenix to incubate in or from the ashes. Indeed it is not the purpose of this paper primarily to make sport either of dermatology or dermatologists, but to touch upon what is known and unknown, to admit our peculiarities and to point out broadly what avenues of thought dermatology may seek to insure its own progress. The foregoing ridicule, were I one to sentimentalize, might easily be replaced by adulation. It might have been said that dermatology, beginning as a science of nomenclature, elevated itself little by little through the influence of microscopic pathology, parasitology, biochemistry, and finally by the subtler application of all phases of all of these. This would be absolutely true, but each stage of advancement has been hampered by inertia, and always that curious inertia of nomenclature. Despite our progress we are still hobbled by Hebra and Kaposi, by the greatest clinicians, perhaps, of all times, but certainly today a retarding influence. A retarding influence, save insofar

as it is axiomatic that a dermatologist must know his Hebra and Kaposi, his Lorry, Willan, Bateman, Calcott and Tilbury Fox, Cazenave, and a host of others, precisely as, to restate the comparison, a composer must know his harmony and counterpoint, his orchestration. Nor should such attainments be hailed as a virtue, but rather assumed as a foregone conclusion, much as we expect a well-bred person to understand the difference between a knife and a fork without dilating upon his discernment. I mention this in passing because there appears to be a growing mania in certain quarters of the United States to ignore a basic fact. No work on dermatology can be accepted unless it may be assumed to be sponsored by people who have mastered the elements and fundamentals of their field.

On this foundation no superstructure, however lofty, of cognate knowledge and attainment will be topheavy. The dermatologist will be the better for understanding all the laboratory, clinical and therapeutic aspects of his subject. The degree and quality of his mastery will depend entirely upon his own talents, training, temperament and intellectual integrity—particularly integrity. This is axiomatic. The laws and customs of man cannot alter this. Science has its roots in ethics, together with religion and all other human spirituality. So much for the nature of dermatology and those professing it.

To return to the opening paragraph of this paper—a case of dermatitis herpetiformis constitutes an intellectual impasse. The nature of the disease is unknown. The diagnostic procedures enumerated have been followed time and again by dozens of dermatologists in scores of cases, and always lead nowhere, but no new efforts are made. Dermatitis herpetiformis is a chronic exudative inflammation characterized by phases of activity and partial remission. Of such a process what forces can determine the behavior? A relapsing infection, a cyclic metabolic disturbance, either biochemical or anaphylactic, a re-exposure to given external factors not unlike those we know about in dermatitis venenata. Does this furnish no clue to future study? I think it does. Almost identical reasoning would apply to all the skin inflammations of unrevealed causation.

For a moment let us pause to narrow the issue. We may exclude from consideration congenital anomalies, neoplasms and frank infections, whether due to animal or vegetable parasites. They are excluded not because our knowledge of their nature is complete, but because it is sufficient to serve as a sound foundation for future building. What remains are the inflammations and dystrophies. Among the former must be included eczema or dermatitis, urticaria, erythema multiforme, psoriasis, parapsoriasis, seborrhoea, the lichens, lupus erythematosus, pemphigus, dermatitis herpetiformis and the exfoliative dermatoses. Among the latter must be included the

atrophies, the hypertrophies, conditions like sclerema of the new born, possibly Darier's disease, and the xanthomas. Besides these two groups the lymphodermas and the telangiectases should be mentioned. Of all of them, the most important are the conditions in the first group because they are the commonest dermatoses and hence those of greatest human significance. Indeed, the remainder of this paper will be confined, for the most part, to allusions to these commoner dermatoses. It would be futile to dilate on the rarer conditions until the day dawns when all medical problems may be encountered with a richer offensive of method.

It is this very restriction in methods of study that is the nucleus of our difficulties, and it is precisely our smug willingness to let common dermatoses go with an appellation that prevents our overcoming that restriction. The vicious circle is established. What we know of the common dermatoses is the following. We fairly well understand their microscopic anatomy. It is clear that a large number of cases of eczema are due to cutaneous hypersusceptibility. It is apparent that many cases of urticaria are anaphylactic phenomena. It is equally apparent that in many instances exudative erythemas are either urticarial or toxic. Arsenic causes a type of exfoliative dermatitis. This may provide an insight into the probable mechanism underlying the other exfoliative dermatitis types, but the ultimate explanation is still remote. Lichen planus is amenable to arsenic and mercury, but arsenic may also cause an eruption resembling acute disseminated lichen planus. A disconcerting paradox! For the rest, our knowledge is nil. Studies in nitrogen and carbohydrate metabolism, analyses of the feces, blood cultures, other parasitologic studies have advanced our knowledge but little. Xanthomatous lesions are associated now with disturbed fat metabolism, now with diabetes, now with neither. Dermatitis aestivalis is apparently associated with hematorporphyrinemia. This is all we know. The question is, where do we go from here?

It is clear that all disease is due to poisoning. The poisons may originate from parasites, from a disturbance of any of the manifold complex and interdependent mechanisms related to or controlling normal processes within the body. Any disturbance of any of these unbalances the whole machine. The delicately adjusted timing of production, utilization, destruction and elimination is upset. A substance beneficial in proper tempo and place becomes a poison. Those catalyzers, the ferments and enzymes, function in a manner out of joint. The prospect is overwhelming. The knowledge to be extracted from Nature, jealously guarding her secrets, is stupendous. And yet Christian vanquished Apollyon and David overthrew Goliath. Puny as man is he can overcome this Titan. Nor is there any limit to the achieve-

ment possible to the concerted effort of mankind.

The beginning of the affray must be simple. The first move must be a changed attitude toward dermatology. As long as naming diseases remains so satisfying the automatic bias will persist that they are best encountered by exorcism. Until psoriasis is regarded not as an enemy to be faced with a rigid stance, but as a process to be courted, analyzed, cozened, human ingenuity will unfold itself to meet the higher, subtler demand. Psoriasis must be due to a parasite or an intracorporeally engendered poison. Has it been investigated by means of the most approved technique of anaerobic culture? Has it been studied as to filtrable virus, to ultramicroscopic agents? Is it not curious that psoriasis has, together with nearly all other dermatoses, peculiarities of localization? Does not this mean a definite, mutual affinity between the pathogenic agent and the consistently affected sites? This may be biochemical or endocrine, and an explanation may possibly be found in live staining. It may be a matter of osmosis at certain cutaneous areas. We older dermatologists may imagine these things, but are unequipped to lock horns with the problem. Some younger man of inspiration now getting his training, if he would only fortify himself in the more abstruse phases of science, will be accorded the revelation, but not if he is content merely to call psoriasis psoriasis when he sees it, and to hold up his hands helplessly when he beholds it. A thousand inspired failures, perhaps, and then success for someone, and a new impetus for others to carry on.

And the same might be said of all the other diseases mentioned. Seborrhea often resembles psoriasis but situates itself differently and is prone to vesiculation. It has all the earmarks of an infection in a peculiarly predisposed host. Is it enough to look for the genui of this malady in the absurd bottle bacillus that is obviously only a saprophyte? There are no thoroughly rounded out parasitologists in dermatology who are also sound dermatologists, except Weidman of Philadelphia. I wonder how he would approach studying Seborrhea. It is not my object to refer to people by name, but I cannot withhold this encomium, for Weidman is an outstanding figure both as to training and imagination in his combined field. The response of lichen planus to parasitocides internally administered, its exanthematous character, its lowering retreat to certain favorite localities which become its obstinate strongholds, suggest a less than remote kinship to diseases caused by protozoa. Cannot some young Hercules now girding his scientific loins make the solution to this problem the first of his labors?

Of all baffling dermatoses, however, the urticarias and eczema remain the worst because they are so common. Anaphylaxis gives the clue to the urticarias, or to some of them, but must the

offending proteins always be considered as having their sources in food? Cannot poisons, working like anaphylactic toxins perhaps arise in the body itself? Duke has pointed out a very subtle type of urticaria. So has Klander. Their's is not pigeonhole dermatology. Their vision has transcended strawberries and clams and that greatest and best advertised hypothesis, focal infections which explain something but probably not one per cent. of that for which they are inculcated. Nor is scratching the skin the last word to be said as to methods of studying susceptibility, nor finding streptococcus viridans at the apex of an infected tooth the last word in clearing up all etiologic enigmas. Urticaria and eczema have this in common more influences external and internal can produce the syndromes so named than produce any other cutaneous syndrome.

Eczema, until within the last half generation, has been our greatest, because it is our commonest bugbear. All of the pigeonhole absurdities have been most conspicuous here. An untenable distinction between eczema and dermatitis venenata has been widely championed. Two processes identical in appearance, behavior, course, microscopic anatomy have been differentiated, because in one group the cause could be determined, and in one it could not. It is necessary only to point out that primrose dermatitis acts just like chronic eczema if exposure to primroses is not avoided. To the logical this should be sufficient. The whole story need not here be threshed out again. Today we know that what is called eczema can be caused by all sorts of chemical agents affecting the skin from without, by fungi, at times by bacteria, or that it can be the result of metabolic disturbances. The writings of Norman Walker, Fordyce, Jadassohn, Johnston, Frederick Harris, Engman and, preeminently, Bruno Bloch bear ample testimony to this fact. The further work to be done would parallel that already outlined in connection with psoriasis.

Pemphigus acts like a chronic infectious disease. Its probable solution will lie in parasitologic studies, but it must be added that the story of pellagra might apply to pemphigus. Would it perhaps be as wise to approach this mystery with some such idea in mind while, pending a solution, we continue treating the disease with however little prospect of cure, along accepted plans. The mere fact that cures are recorded under intensive arsenic administration supports the hypothesis of infection. Photosensitization plays a role in dermatitis aestivalis and lupus erythematosus. In the former hematuria has been determined. May there not likewise be such a factor in erythematosus lupus? Is there not such a factor in pellagra? Should we not look for grouped interoperating causes in disease, a toxin and a precipitant like the actinic rays?

Enough has been suggested to indicate a possibly fruitful attitude toward the problems of

cutaneous medicine. I am satisfied that our approach thus far has been too limited. To find hyperuricacidemia in a majority of this, that or the other group of dermatoses, or hyperglycemia, means rather an association of two morbid phenomena than a casual relation between them. Their key must be a single, consistent and specific finding. This has never yet been discovered, save in infections. Again let us turn to the dilemma indicated in the opening paragraph. What is gained in studying a case if we go through all the manipulations we can think of, when we know that none of the possible positive findings are peculiar to the disease. It is specific relationships we are seeking, definite morbid alterations, invariable abnormal associations.

The surface area of the skin is just under two square yards. The skin is the physical, physiological and chemical barrier between all that it contains within itself as an envelope, and the outer world. Its functions are manifold and complex. It is capable of morbid manifestations peculiar to itself and morbid manifestations reflecting internal disturbances. Hence it follows that there are two groups of skin diseases, the purely local and the internal. It is important to differentiate between the two. Time, enlightenment and imaginative study will enable us to. Routine studies, beginning with the bow-sprit and ending with the rudder are, in themselves, pigeonhole activities. They are comprehensive but undirected, diffuse and hence aimless. They may unearth a truth, but only by chance. In a case of impetigo it is more sagacious to look for pediculosis capitis than to determine the patient's basal metabolism. I have seen a patient with scabies nearly starved to death by a physician who found the blood uric acid coefficient too high.

The essentials to such progress are first an astute and accurate clinical appraisal of dermatoses. Next, all known methods of analysis must be essayed if no easy explanation of the case comes to hand. Third, a few unthought of procedures must be thought of. An ideal dermatologist would have the eyes of Hebra, the depth of Virchow, the ingenuity of Claude Bernard, the imagination of Pasteur, the common sense and intellectual integrity of Osler and the courage of Jesse Lazear. There is no such man. But all dermatologists cooperating and mastering their own narrow field, and at least one other related field would ultimately rear the science we all dream of. Is this dream idle? Leonardo di Vinci dreamed of airplanes four centuries before there were any. He understood principles of modern geology over three hundred years before Lyell was born. Let us dream these dreams. Human progress is merely dreams of one era come true in a later one.

Man is a self-contained microcosm in which occur such of the universal physical and clinical phenomena as are required for life. Among these

requirements is the important one of organic self repair. Thus the living being probably possesses closely related mechanisms for maintaining and restoring health. These must cooperate with all other body functions according to general laws governing the forces and matter involved. The various systems of organs could not contribute their respective parts unless the finer control of the sympathetic and autonomic nervous systems functioned, unless the various enzymes, ferments and endocrine substances smoothly played their subtle roles. To what extent physico-chemistry is involved we can scarcely surmise. Nor can we yet surmise when interference with osmosis, dialysis, diffusion within our tissues may be the inconspicuous start of a serious if not fatal malady. It is in terms of a growing comprehension of remote activities in fields not yet brought closely enough to medicine, that the ultimate nature of disease must be sought. The investigator of to-morrow must be a physicist and chemist as well as a physician. The first dermatologist who is such a physician will be the first to solve some of the problems of dermatology. He may not be a practitioner, but even practitioners will then have to be better trained than now to keep pace with the growth of actual knowledge. They will probably look back on contemporary dermatology with that amusement, and perhaps with some of that awe with which we regard precocious children, but they may wonder why we so long stayed children.

It remains a constant source of astonishment to me that the skin, the greatest organ available for study while its owner continues alive, is the one which has interested fewest physicians. Moreover it is the one about which, to state it conservatively, no more is known than about internal organs. Internal organs are not readily studied until after death, or if during life, without extensive manipulation and preparation. A few simple modifications in our approach to this would initiate a change, and time would make the change complete. The first consideration must be a more open attitude on the part of dermatologists toward their specialty. The second is a question of the nature of the dermatologist's general scientific, general medical and special training.

The attitude of dermatologists requires broadening. The physiology of the skin needs a complete review from the standpoint of the relation of the sympathetic and autonomic nervous system to the cutaneous vessels, to the sebaceous and sweat gland function and to the normal growth balance of the epidermis, papillary body and corium. The chemistry of the skin secretions and excretions must be studied anew. Anatomic and physiological differences of the different skin areas must be worked out. Perhaps better methods of live staining will further this. The chemical balance between the skin and kidneys must be re-examined. A new normal and morbid his-

tology of the skin must be written in terms of live staining, the hydrogen ion content, and with the idea in mind of the skin's being, among other things, a membrane in which phenomena of dialysis and diffusion require investigation. Next, dermatologists, while at first retaining the old nomenclature, must try to reclassify cutaneous pictures less with the dictionary in mind, than with the findings garnered from the new methods of analysis recorded above.

Basically, at the start, the new dermatologist must remain an old guard observer with a keen eye to the future. If this be not emphasized a hiatus will develop separating the newer work from what it is its object to clarify, and confusion will arise. The fetish of diagnosis by inspection, together with all other forms of pigeon hole dermatology, must be abandoned. The concerted effort of all dermatologists of today should be directed toward the training of younger dermatologists to outstrip their teachers both in clinical accuracy, scientific versatility and unstilted imagination. Clinics for the treatment of cutaneous diseases should be better equipped for study and less hurriedly conducted. Hospitals should have bigger wards for patients with skin diseases and more sympathetic laboratories. At society meetings more emphasis should be placed on analysis of than on naming cutaneous maladies. Speakers stating their impressions and views in discussion should be rigorously held to substantiation by fact and experiment. Fewer cases and papers should be shown and read, but more ample exchange of ideas should be cultivated. Editors of special journals should have these principles in mind in accepting contributions. This is only an incomplete sketch of what might be a beginning but it would more than start us aright if the embodied suggestions proved feasible.

The dermatologist's training should begin as any other physician's. Premedical requirements should include chemistry, physics, biology and botany. The principles of organic, colloid and physiological chemistry should be included. It may appear gratuitous to others, but to me it seems important that premedical courses in higher mathematics and logic should be demanded in order that physicians may acquire the mode of deductive reasoning. The medical school should base its pedagogy on these principles and equip its students rather for constructive thinking than to shine in examinations for internship. The shining would ensue automatically after such preparatory polishing. The special training should include clinical and all associated aspects of dermatology, and no hospital or medical school should regard a man as a dermatologist unless he has satisfied these requirements. Humanity will rise to any intellectual level set by its leaders, and it is within the power of institutions to pitch their standards as high as they will without fear that individuals will be lacking to meet them. The

supply will rise to the demand if the demand be sincere and the leadership competent

Two groups of dermatologists will be engendered, those who lean more to research, and those who lean more to practice. But the two must understand each other and no such distinctions may be allowed as "scientific" and "practical" dermatologists, for the latter also are expected to be scientific. It is not that the two represent different arts, but that each masters a different application of the same art. Those with a taste for research are practitioners of social medicine. They labor for humanity in the abstract. Those with a taste for practice labor for particularized humanity. The basic requirements for each are identical. That economic factors may not lose research workers for society their remuneration should be raised to a level compatible with rearing their families in reasonably easy circumstances. This is no exorbitant demand if the community wants to guarantee itself that progress which its physical welfare demands. A high degree of excellence must in some way be paid for and a high degree of excellence in der-

matology is with what this paper concerns itself

The end approaches. Lest this paper seem patronizing may I state that it is mainly inspired by sensitiveness on my part to my own limitations. Premedical and medical training in my student days lacked those elements, the need of which my later experiences made clear to me. The wonder remains that all of us who perforce suffered similar intellectual disabilities have blundered forward as far as we have. We have infinite capacity for better things, and we have all been infinitely handicapped. That this should not remain so is my hope. There may be nothing of practical value in the suggestions herein embodied, but tearing them to pieces may lead more astute thinkers to sounder conclusions and plans for a better, more fruitful training for future dermatologists. May the weight of tradition be lifted from the shoulders of the oncomers! May they study the past to escape it and achieve a more liberal future! May that future be one in which the pigeon hole concepts, biases and rituals that cloud today give way to a clearer, more luminous dermatology for to-morrow!

## THE IDENTIFICATION OF AUTHORS

The signature on a paper offered for publication in a medical journal is as important as that on a bank check or note. The editor must be assured of the personal resources and responsibilities of an author.

The normal identification of an author and his resources is the endorsement of the officers of a medical society. But the JOURNAL often receives papers which bear no identification of the profes-

sional standing of the author. The writers of these papers must be identified before this JOURNAL can accept the statements of the unknown authors.

The usual procedure of an author is that he shall read his paper before a recognized medical society, and shall present evidence of its favorable reception by the members of the society.

## DOCTOR LEONARD WOOD

General Leonard Wood, physician, military leader, statesman, died on August 7th, aged 67 years. Inheritance had a place in the determination of his abilities and temperament, for his father was a physician and officer in the Civil War. Graduating from the Harvard Medical School in 1884, he entered the Army as Assistant Surgeon January 6th, 1886, and at once showed military abilities and activities which at that time were considered incompatible and unnecessary for an army doctor, but which today are demanded of a medical officer. For conspicuous service in the strenuous pursuit and capture of Geronimo, Dr. Wood received the Congressional Medal. When the achievement of Dr. Wood is considered in the light of today's organization and authority of the Medical Department of the Army, it would appear that one of the essential elements in the success of that Indian campaign was the medical procedure which Dr. Wood put into practice for the conservation of the health and strength of the soldiers.

Dr. Wood was a good practising physician—his appointment as White House physician by President Cleveland and his retention in that post by President McKinley showed that, but he also had a superlative degree of prophetic insight, and constructive leadership, which led him to anticipate the recognition of the Medical Department of the Army which came only with the World War. The Medical Department of a modern army demands the highest qualities of military leadership, and if General Wood were starting his army career today he would find abundant opportunities for the exercise of all his knowledge and skill

if he confined his activities to the medical service only.

The solution of medical problems entered into the success of General Wood to a far greater extent than is usually realized. As Military Governor of Cuba from September 24, 1898, to May 20, 1902, General Wood gave his active support to those investigations which resulted in the discovery of the mosquito of yellow fever and to the suppression of the disease on the Island when only military power could enforce preventive measures which then seemed both ridiculous and burdensome.

General Wood was the father of the system of military preparedness under which the majority of the American officers, including 30,000 medical officers, were trained during the World War, and over 1,500 Medical Reserve Officers are undergoing military training this summer.

The Medical Field Service School at Carlisle, Pa., that is described on page 857 of the August 1st issue of this JOURNAL, is the direct outgrowth of General Wood's preparedness program.

The success of General Wood's administration as Governor General of the Philippines, in which he was engaged at the time of his death, was greatly helped by his promotion of the eradication of leprosy and the establishment of a treatment station on the Island of Culion about two hundred miles south of Manila. (See this JOURNAL May 15, 1927, page 566.) One of the last acts of General Wood was an appeal for a two million dollar endowment in aid of the station.

General Wood was the incarnation of the broad principles of the practice of public health and civic medicine.

---

## THE NEW ENGLAND MEDICAL COUNCIL

The Medical Societies of the New England States are proposing to follow the example of those of New York, New Jersey and Pennsylvania, and to establish a series of conferences among the representatives of the several state societies. While the Tri-State Conference of the Middle States is informal, and is not governed by rules or by-laws, that of the New England States is planned along more formal lines. A description of the plan is set forth in the Annual Report of Dr. B. L. Bryant, the Secretary of the Maine Medical Association, which appears in the May issue of the Journal of the Maine State Society.

The plan seems to have originated with the New Hampshire State Society, and has been endorsed by New Hampshire, Massachusetts, Rhode Island and Maine. Its proposed constitution provides for five representatives from each state, and for two meetings each year.

It is also proposed that the six New England States join in the publication of one medical journal. Proposals to that effect have hitherto met with little response, and the result has been that Maine, Massachusetts, and Rhode Island are the only New England States that have their own medical journals. The union of all six states in the publication of the Boston Medical and Surgical Journal has met strong opposition because when the control of the Journal was given over to the Massachusetts Medical Society, the stipulation was that the present name should be continued until the Journal should have completed its 100th year, which will be in 1928. But negotiations are now under way that the Journal shall become the official publication of each State Society and the cost be borne pro rata according to the membership of the several organizations.

## THE INHALATION OF BABY POWDERS

It is well known that pneumonia and death may result from the inhalation of toilet powders used on babies. Fatal cases have been reported with such frequency that surely the manufacturers of the powders must know the dangers of the inhalation of their products. Yet the manufacturers of a well-known brand of dusting powder fill a large outdoor bill board with the picture of a lusty infant lying on its back and holding aloft a can from which a stream of the powder is pouring over the delighted infant's face. If this actually occurred, the baby would probably be dead of inhalation pneumonia within twenty-four hours.

A placard often seen in street cars shows a baby toying with a can of toilet powder whose name appears in prominent letters. While this advertisement does not show the powder pouring from the can upon the baby's face, yet the menace is still there.

Pediatricists go to great lengths to warn mothers against allowing their infants to play with the box of toilet powder. It seems strange that manufacturers disregard those warnings and show attractive pictures of babies innocently committing suicide.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*On Doctors' Sons*—This JOURNAL for August, 1907, contains the following comment on the sons of physicians who adopt their father's profession—EDITOR'S NOTE

Doctors' sons pretty generally make good doctors, that is, if they decide to study medicine and be doctors at all, they succeed. When you hear a physician say that the practice of medicine is a dog's life, and that if he had it to do over again he would never study medicine, that patients are ungrateful and give him little thanks or pay, you may be pretty sure that his son will not study medicine, and if perchance he should, he is terribly handicapped by a lot of bad medical traditions. The unsuccessful doctor does not let his son study medicine. The doctor's son who does study medicine is quite invariably the son of the man who was successful enough to find joy in his work, and who could wish his son nothing better than to enter into the calling which had meant so much to him. And the boy saw in his father's life something that excited his admiration to emulate and covet. As a matter of fact and observation the son of the really successful doctor commonly does study medicine,

and I can name a number of such men who attained to even greater success than their fathers.

That the doctor's son takes his cue from his father, and that the father should be careful of what he teaches his son, even inadvertently, is illustrated by a homely example. The one man in this country, who is devoting himself assiduously to calumniating and misrepresenting medicine, is the son of a doctor—a well-meaning man, still engaged in mildly practising his profession. This good old doctor is a frequent contributor and a professed admirer of one of the most disreputable medical periodicals charged up to the account of American medical literature—let us be accurate and say *the* most disreputable. That means that the son gets an impression of medicine from the literature which he finds on his father's library table. I presume that the son judges that this so-called medical journal represents the medical profession because it says it does and because it contains the pictures of many men of good and high standing who intersperse its advertising pages with the products of their agile pens, innocently and little knowing of the damage they are doing.

# MEDICAL PROGRESS

**Agranulocytic Angina**—In a review of the literature on agranulocytic angina George J. Kastlin collected 43 cases to which he adds two typical cases. These correspond closely to the description of the condition of Schultz, in 1922, who states that the disease is characterized by a severe stomatitis and unusual blood picture occurring in women past middle age with negative past histories. It is manifested by sudden rise of temperature, sore throat, dysphagia, chills, and malaise, which progress to severe toxemia and prostration. The symptomatology is not constant, though stomatitis is always present. There may be regional adenopathy and enlargement of the liver and spleen. Jaundice is common while petechial hemorrhages are rare. The blood change of neutrophilic leucopenia with relative lymphocytosis is always seen. These blood changes are the result of the primary action of an unknown etiological agent on the bone-marrow, which at autopsy is grossly red in color, while on microscopic examination it is cell-poor with almost complete absence of granulocytic cells. Because of the peculiar damage to the granulocytic blood cells associated with stomatitis, Schultz gave it the name of agranulocytic angina. The ulcerative sites in the mouth and at various locations arise secondary to the blood changes, due to decrease in the body resistance to infection. The ulcerative sites show a lack of the cellular response of inflammation. This same lack of cellular response is seen in the pneumonic process which usually leads to death. The disease does not always terminate fatally. On recovery the blood picture returns to normal. One attack of the disease does not protect against a second attack. Differential diagnosis in agranulocytic angina presents points similar to the reactions to specific poisons, lymphocytic leucemia, alymphatic leucemia, and cases of sepsis with leucopenia. It does not fall within the classification of these conditions but with the evidence at hand it cannot be called a clinical entity. In Kastlin's cases there was no definite jaundice. Cultures of the mouth were negative for the diphtheria bacillus and positive for the hemolytic streptococcus. They also revealed spirochetes, one of the Vincent type, the other a bifidus-like organism. The blood pictures all presented leucopenia, decrease in the polymorphonuclear leucocytes, a relative lymphocytosis, and increase in the endothelial cells. The bone-marrow showed the changes above described. One of the cases was serologically syphilitic while the other

revealed a tuberculous process in one kidney.—*American Journal of the Medical Sciences*, June, 1927, clxxiii, 6

**Tuberculous Endocarditis**—A. Pic and L. Morenas of the Medical Clinic of the University of Lyon write at length of this little known condition which has nothing in common with actual tuberculosis of the endocardium, this last being particularly rare and of little clinical importance. The affection in question is known mostly to the pathologist who finds, at autopsies on the tuberculous, sclerous cicatrices of the endocardium, whether parietal or valvular, but it is now and then detected by the clinician, despite the latent character. More apt to occur in the child, it sometimes is masked as ordinary rheumatic endocarditis with its sequelæ in adult life. It may occur as a vegetating endocarditis and shows much polymorphism as to the lesions encountered at autopsy, with nothing characteristic of its tuberculous nature excepting the discovery of Koch's bacilli in certain of the lesions. The diagnosis is wholly inferential *in vivo* and we may suspect the disease in young tuberculous subjects under certain circumstances and in acute rheumatic affections in which salicylic acid is inert. In rare cases the presence of Koch's bacillus in the blood seems able to set up both the acute and slow types of sepsis, and here septic endocarditis is mimicked. Unfortunately the authors do not cite a single case, much less a series of illustrative cases, so that it is difficult to visualize the disease. However, they have in press a volume on "Tuberculosis and the Cardiovascular Apparatus" of which their article is apparently a condensation, which will no doubt supply this omission.—*Journal de Médecine de Lyon*, April 20, 1927

**Treatment of Intermittent Lump**—Kurt Mendel at the request of the editor of the *Klinische Wochenschrift* prepared a paper on the causation and treatment of intermittent claudication which is to be found in the issue of May 21, 1927. He sums up the causal treatment as being directed against lues, nicotinism, alcoholism, arteriosclerosis, gout, and diabetes, if one or more of these conditions is in evidence. Irrespective of causal indications we may make use of iodine, strychnine, arsenic, quinine, and various diuretics and heart stimulants (strophanthus, digitalis, diuretin, theobromine) while the most important group among the drugs is the vasodilator, especially sodium nitrite. Drugs may also be required

for the severe pain. The entire range of physical resources has been recommended although harm as well as good may result from some of these, and Schlesinger warns against any form of heat. Under operative treatment the Leriche method of periarterial sympathectomy is recommended in difficult cases, but too much must not be expected of it, and the benefit which sometimes follows may be due in part at least to some of the other remedies employed. It is singular to find no mention of the Lorenz-Doppler method of phenolization of the peripheral sympathetic which has been under trial in Vienna for the past two years or more. The author wrote a monographic study of this disease in 1922 and his bibliography shows that he has hardly touched on the literature of the past two years. The allied subject of thromboangitis obliterans is barely mentioned.

**The Appendix Reflex**—A. B. Mitchell, writing in the *British Medical Journal*, May 28, 1927, No. 3464, states that the appendix reflex, giving rise to pyloric spasm, followed by hyperacidity and symptoms suggestive of gastric or duodenal ulcer, is now well recognized. He reports a series of cases which indicate that in certain subjects, with unstable nervous system, a diseased appendix may be the exciting cause of symptoms of an entirely different character. In three of these cases the symptoms were those of migraine, in two cyclic vomiting with acidosis, and in two the patients suffered with epileptic attacks. In two of the patients complaining of migraine there was absolutely no history suggestive of appendix or gall-bladder trouble, in the third case there was glycosuria associated with indigestion. The cases of cyclic vomiting with acidosis occurred in children aged respectively 10 and 6 years. In commenting on these cases Mitchell says that appendicitis in children is much more common than is generally recognized. He believes the majority of cases of so-called colic are primarily appendical, and that a large proportion of the cases of so-called chronic appendix which are met with during abdominal operations have originated in early childhood. In the "nervous child" such an appendix may give rise to a variety of reflex symptoms, even in the absence of any local sign. In the patients with epileptic attacks there was a history of indigestion and in one instance of abdominal pain. All of these patients were entirely relieved of their complaints following appendectomy. This group of patients, who may be classed with the subjects of hysteria, neurasthenia, and certain cases of mental disease, have one feature in common—that is, a nervous system which is liable to be upset by some slight reflex stimulus. A thorough

examination for an abdominal focus should be carried out in every instance. A misplaced uterus or a movable kidney will often afford an explanation, but a diseased appendix will prove to be the exciting cause much more frequently than has hitherto been suspected. Mitchell wishes it clearly understood, however, that he is not proposing that every sufferer from migraine, cyclic vomiting, or epilepsy should be submitted to an appendectomy.

**Endocrine Treatment of Psoriasis**—A. Buschke and W. Curth of the Rudolf Virchow Hospital, Berlin, state that many attempts have been made to base a treatment of psoriasis on presumptive anomalies of metabolism, and in this connection they recall the favorable results from giving thyroid substance in certain cases. Buschke has recently seen a brilliant result of this kind. After radiation of the thyroid had been shown to have little value the thymus was rayed instead with results so promising that the method was soon extensively tested, but on the whole with disappointing consequences. Remarkable isolated cases of cure with thymus tablets or injection of thymus preparations have been reported. The authors have x-rayed the skull in many cases of psoriasis in order to determine the presence or absence of anomalies of the sella and irrespective of the state of the latter occasional good results have been seen from the exhibition of extracts of hypophysis. So far as known no other of the hormone producing structures has yielded any benefit in psoriasis. It can only be said at present that in certain cases in which there is presumably a deficit in some internal secretion positive results can be obtained by supplying the deficiency. The favorable action of the hypophysis extract is most likely associated with a double deficiency of the hypophysis and ovary. In the treatment of a given case every effort should be made to locate any possible hormonal deficiency, for in some of the more striking cases recorded accessory measures were not required. For the present we must still cling to the old remedies—chrysarobin, tar, arsenic internally, baths, and local roentgenization.—*Deutsche medizinische Wochenschrift*, May 6, 1927.

**Pilocarpine in Postoperative Urine Retention**—H. M. Hinrichsen refers to the cases of this nature in which there is fear of infecting the bladder with the catheter. As a rule one or two passages of this instrument is sufficient to dispose of post-operative retention. It is of course true that urotropin and one of the more recently introduced urinary antiseptics may be given before operation. The idea of intravenous injection of pilocarpine is borrowed from Lampert's study of the action of

the drug on animals, but itself may be regarded as an additional surgical intervention which might have as unfavorable results as the catheter. A French author, unnamed, seems to have made use of pilocarpine subcutaneously, but Hinrichsen mentions no clinicians who have anticipated himself. He has used the resource thus far in 38 post-operative cases and obtained 100 per cent of good and safe results. But little reference is made to the dose which appears to have been 0.01 gm. Collateral symptoms of heat, lacrymation, hyperidrosis, etc., were not burdensome to the patients. The author would not make use of this resource until the fundus of the bladder has risen three fingers' breadths above the symphysis. A second injection was required in only a few cases. The author's cautious attitude is based on the statement found in some of the systematic works on pharmacodynamics that collapse occasionally develops after the intravenous injection of pilocarpine. Lampert in his recent study denies that bad effects develop but the author would proceed with great caution in nephritic and arteriosclerotic patients.—*Deutsche medizinische Wochenschrift*, May 29, 1927.

**A New Record in Consecutive Laparotomies**—Margarete Liebers believes that she may have beaten or at least equalled the record for the greatest number of laparotomies performed on a single patient. She is able to report no less than seven such interventions. These multiple operations are necessitated in cases of erroneous diagnosis, as of appendicitis in cases of tabetic crises, in repeated cesarean sections, in simulation of ileus, etc., to get into hospitals (the author quotes such an experience in a young man of 20 who had already been operated on five times), and in the insane who swallow foreign bodies. Her own case was of the latter type, in a man of 24, constitutionally inferior and psychopathic, a criminal, a morphinist, and with suicidal tendencies. The motives in swallowing nails, etc., were mixed—to avoid punishment, to obtain morphine, etc. Of the seven operations six were performed in succession in the same prison during a period of two years while the seventh followed in the psychiatric asylum after transference. The operations were not simple gastrotomies, for the swallowed objects reached the small or large intestine before furnishing immediate indications to operate. Fistulous communication with the small intestine was left after three of the laparotomies. Owing to the large number of adhesions which formed as a result of the foreign bodies or operation, intervention became more and more difficult, as neither the small nor large intestine could be mobilized.—*Münchener medizinische Wochenschrift*, May 13, 1927.

**The Treatment of Ankle and Foot Sprains**—Frank Thomas Woodbury, writing in *Physical Therapeutics*, June, 1927, xlv, 6, calls attention to the revolutionary changes in the treatment of uncomplicated sprains brought about by the advent of physical therapeutics. Though the advantages of these changes have been established by those using physical agents for about thirty years, the general bulk of the profession have been contented with the methods of their fathers. The employment of physical agents in the treatment of sprains of the ankles and feet is chiefly a sequence of diathermy—the static wave or static brush effluve from a wooden point or a deKraft electrode, positively grounded, to be followed where there is much muscular spasm by static sparks from a negatively grounded ball electrode, and finally full use of the joint at once without any supporting dressing. In cases with much hemorrhage the static wave is given alone or the brush effluve may be substituted with equally good effect, the treatment lasting not less than twenty minutes and possibly an hour. The use of any sort of a support has been found unnecessary with this method, as the relief is immediate and the patient can use the joint at once, which is an aid in the recovery. Adhesive strapping is a deterrent of the free use of the joint and should be used only in the case of a very heavy person or of a very severe sprain, and then only for the first twenty-four hours. Nothing will so soon produce ankylosis as immobilization by strapping, splints, or casts. Even the customary advice to rest the joint defeats the free motion which produces a natural form of tissue massage which removes exudates and restores circulation. The treatment of old sprains when ankylosis has already occurred is a very different matter.

**Temporary Strabismus Following Vaccination**—C. Saloz and E. Frommel relate the case of a postvaccinal episode in a girl of 16 on the ninth day following a revaccination. The total duration of the anomaly was 27 days and recovery was complete. The case would have caused little attention were it not for the fact of postvaccinal encephalitis, a few cases of which have come to light during the past two years, in one of which, reported by Comby of Paris, encephalitis had begun with strabismus. The present case developed on the ninth day after a successful revaccination. The strabismus was of the right eye and divergent. There was slight inequality of the pupils and a little trismus. Some fever had developed from the vaccination but it did not go above 100.4°F, and the patient had for several days complained of headaches. Lumbar puncture revealed no sign of infection. The patient did not at any time present any evidence suggestive of encephalitis although there was doubtless a slight meningeal reaction. Probably the condition was a mild type of postvaccinal cerebral complication, such as is known to develop,

although with extreme infrequency, from vaccinia, variola, varicella, and other infections not of this group. As it is easy to exclude the presence of a special virus in the vaccine the essential factor must be the oversensitiveness of the patient to an ordinary infection, which is not limited to the pock-like diseases. Cases of encephalitis have recently been reported after measles and it is believed that racial susceptibility to this lesion has increased greatly during recent years.—*Schweizerische medizinische Wochenschrift*, May 14, 1927

**Cervical Rib**—Alfred W. Adson and J. R. Coffey (*Annals of Surgery*, June, 1927, lxxxv, 6) describe a method of anterior approach for the relief of symptoms due to cervical rib by division of the scalenus anticus muscle. The incision is somewhat similar to that used for the midcervical approach, except that it extends forward and mesially over the sternoclavicular articulation and thus permits mesial reflection of the clavicular attachment of the sternocleidomastoid muscle. The fat and subareolar tissue in the supraclavicular triangle are reflected upward and laterally. The dissection is then carried upward into the lower border of the posterior triangle, exposing the plane of the carotid sheath mesially, the anterior surface of the scalenus anticus muscle, with the phrenic nerve, the lateral portion of the subclavian artery, and the brachial plexus. The transverse cervical and suprascapular arteries are ligated and divided. On observing the relation of the tendinous attachment of the scalenus anticus muscle, subclavian artery, and the brachial plexus near the cervical rib, one is able to demonstrate how the scalenus anticus muscle compresses the subclavian artery to from one-half to one-third its normal size. Tenotomy is then performed on the scalenus anticus tendon at its attachment. At first the authors removed the cervical rib, but later they found that this was unnecessary, inasmuch as the subclavian artery and brachial plexus were immediately relieved of pressure and irritation upon severance of the scalenus anticus muscle from its insertion. The anterior approach and tenotomy of the scalenus anticus muscle are preferable to the transcervical approach and resection, since the same relief is afforded, the procedure is less formidable, and postoperative numbness in the arm and palsy of the brachial plexus are avoided. In 54,413 new patients examined at the Mayo Clinic from June 1, 1910, to Oct. 1, 1926, cervical rib was diagnosed in 303 cases, an incidence of 0.056 per cent. In 167 cases the cervical rib gave rise to no symptoms. Such patients should not be informed of the accidental findings, as the knowledge that such a condition exists may give rise to a neurosis. Surgical intervention should not be advised for mild indefinite pain in the neck and shoulder

**Diverticulosis and Diverticulitis of the Large Intestine**—In an article in the *Practitioner*, June, 1927 (cxviii, 6), F. de Quervain, on the basis of his experience with a dozen cases, describes the different pathological processes associated with diverticulosis and diverticulitis. He shows that these conditions cannot be differentiated by clinical symptoms from colitis of the spastic or of the hemorrhagic form, from perforative pericolicitis and periproctitis, acute perforation into the free peritoneal cavity, and chronic stenosing diverticulum tumor. There are only two methods of investigation by which a diagnosis can be definitely established, namely, rectosigmoidoscopy and x-ray examination. In rare cases the rectoscope allows a diverticulum opening to be seen directly but as a rule the examination is beset with difficulties which detract from its usefulness. De Quervain has been able to make the diagnosis on the basis of the x-ray findings in a number of cases. This is best done by an investigation of the contrast enema, after thoroughly emptying the large intestine. Examination after a barium meal per os is not satisfactory. The x-rays show the diseased section usually rather narrower than the normal adjoining parts. On account of the spasm, it sometimes exhibits that marked pattern of the folds of the mucosa which de Quervain has termed the accordion form. Lastly, some of the diverticula will be found to be filled with the opaque fluid, and are consequently easily recognized as such. In patients with the greatest degree of stenosis, in whom even a thin barium suspension cannot pass above the constricted site, the roentgenographic examination fails to establish the diagnosis. Patients with no symptoms, or those with only mild symptoms of the type of a spastic colitis should not be subjected to operation. If the disturbance be marked, if there be much hemorrhage, or if attacks of obstruction have already occurred, operation is the only treatment possible. On the basis of experience reported up to the present time, resection of the diseased portion of the intestine is the ideal operation. But it is only ideal when the whole segment of the large intestine affected by the diverticula can be removed without difficulty. In a number of cases, particularly in obese patients, operation must be limited to short-circuiting the diseased section of the intestine by enteroanastomosis, unsatisfactory as this maneuver may be with regard to preventing perforation. In especially difficult cases it may be necessary to establish an artificial anus or even to remove the entire sigmoid colon and implant the transverse colon into the rectum. If there be a rectovesical fistula present, an operation should not be decided upon in too great a hurry, since such fistulae may close spontaneously, as occurred in one of the author's cases.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## THE PRACTICE OF MEDICINE AN EXTRA HAZARDOUS UNDERTAKING

The subject of this editorial is an old one, and yet your counsel feels it his duty now and again to call it to your attention

In his Annual Report for 1927, the writer referred to his report of the previous year wherein he wrote

"Perhaps it might not be out of place here to notice how fortunate the doctors have been thus far in avoiding large verdicts. The trend of the times in every other field of negligence law is unquestionably towards larger damages where juries find in favor of the plaintiff. The present value of the dollar is always taken into consideration, so that it is safe to say where a jury ten years ago might have rendered a verdict for ten thousand dollars, it will now award double that sum or more. Juries have become increasingly liberal with the money of defendants in every other field of negligence cases when they find against them."

Recently our attention was directed through the public press, to a notice of the largest verdict which is known to have been recovered in any tort action in this State. A verdict in Mr Justice Edward J McGoldrick's Part of the Supreme Court was rendered in favor of a plaintiff (who happened to be a member of the medical profession) for \$250,000 00. It seems that the plaintiff in that case had been struck by a bolt while a passenger on an I. R. T. subway tram. The plaintiff had been a surgeon at the Skin and Cancer Hospital and the Presbyterian Hospital. He was blinded. The bolt which caused the injury struck his left eye. After losing the sight of his left eye a sympathetic condition developed in the right, resulting in total blindness. The plaintiff had been the recipient of an income of \$150,000 00 a year before the accident and had a distinguished record as a physician. During the war he performed more than 3,300 major operations on soldiers, including an operation on the second American soldier to be wounded in the fighting. The jury listened to his evidence, he was the only witness for the plaintiff and awarded him a quarter of a million dollars for his damage. No one could consider this case, the earning power of which the plaintiff had been deprived and the terrible nature of the injury which he received, without feeling a strong sympathy for him and a satisfaction that

justice was so abundantly accorded, yet, as one considers the amount of this verdict, it is impossible not to appreciate that the tendency of the times and the present value of the dollar are resulting more and more in larger verdicts in tort actions of all kinds. The writer has recently examined into the authorities on this subject and among many other verdicts would call attention to these

Within the last few months, before Mr Justice Gavagan in the Bronx, a married woman who had been seriously injured in an automobile accident was awarded \$65,000 00 by the jury,

In a recent case, the plaintiff suffered from burns from a high voltage wire resulting in the loss of both arms, he sued the railroad company and recovered a verdict of \$55,000 00,

In another case against another railroad company, a five-year-old child recovered \$10,000 00 for the amputation of a foot,

In another, a railroad fireman suffered an injury which resulted in the amputation of his leg, and recovered a verdict against a railroad company for \$20,000 00, which, however, was subsequently reduced to \$12,000 00, as it was held that the plaintiff was entitled to workmen's compensation,

In two other accident cases \$20,000 00 was awarded in each case for the loss of a leg,

In another accident case \$32,500 00 was obtained for the crushing of an arm at the shoulder,

In another case \$25,000 00 was awarded for the loss of an arm, while in still another case a brakeman twenty-seven years of age, received an injury consisting of a broken leg and a fractured pelvis, and the jury awarded him \$22,500 00,

In one case a factory employe of a motor company received \$25,000 00 for loss of vision, while in a similar case \$15,140 00 was awarded for the loss of sight in one eye,

Very recently a middle-aged business man earning \$10,000 00 a year was killed and his widow was awarded \$40,000 00, while in another case a musician forty-six years of age was killed. He had an earning capacity of \$4,200 00 a year. His administratrix obtained a verdict of \$30,000 00,

In a case against one of the city railroads a business man 62 years of age, with an earning capacity of \$25,000 00, recovered a verdict of \$27,500 00,

In a case against a traction company of this city, a fireman thirty-eight years of age was killed, his earning capacity was \$3,300 00, yet his widow recovered \$25,000 00

These are but a few instances of the many which could be cited. Of nearly 400 cases undisposed of in your counsel's files there are many cases in which the damages sought are in excess of \$100,000 00. More than one-half of these cases seek damages in at least half that sum. In many of the cases now on file it is claimed that death was caused through a doctor's fault, in others, loss of sight in one or both eyes, while in still more, injuries resulted from alleged improper treatment of fractures. The cases now pending in the writer's hands embrace claims involving nearly every injury and disease to which the flesh is heir.

A jury is a fickle thing. That no one can tell what a jury will do is more than a platitude. It is a statement of the exact truth. Even where the doctor feels that he has not been at fault in any way and where his experts agree with his position, and where your counsel to the best of his capacity, seeks to uphold, sustain and justify the doctor's course, on the theory of chances, it is inevitable that he cannot always be sustained.

The writer feels that the medical profession may take a just pride in the small number of verdicts which has been recorded against any of their members, and yet some adverse verdicts are bound in the future to occur as they have happened in the past. No doctor is infallible, no doctor is perfect, he is only a trained human being doing the best within his power, but even the most trained, conscientious and experienced man will err. This is true of engineers, lawyers, statesmen and business men, it is equally true of the medical profession. It is the fair and honest recognition of these things which led to the inauguration and maintenance of the Society's group plan. By means of this, not only does the assured receive the benefits of your counsel's services, but the assistance and cooperation of the trained investigators of the insurance carrier throughout the State. And, of course, above and beyond all this, if in any case the jury should decide against the doctor, that doctor if insured is financially protected, and the judgment is paid by the insurance carrier rather than by him. The benefits of this group plan have been frequently expounded and have received and are receiving an increased appreciation from the medical profession.

More, perhaps, than the doctors themselves

appreciate, the medical profession is misunderstood by many of the lay public, especially, of course, among the more ignorant members of that public. This ignorance results in many malpractice actions without merit which should never have been begun. It results in supposed grievances which are without real foundation but which eventuate in court actions. The fact also should not be forgotten that not every action brought is totally without merit.

A short time ago, the writer called attention to the murder of Dr. Pendola by an ignorant and inflamed Italian. A similar case was but recently recorded in Pennsylvania. There it seems that Dr. Frank Fisher Moore of Homer City, some seven years ago, was called to treat one John Ammorian, a coal miner, whose back had been broken in a mining accident. The surgeon operated and his associates marvelled that he saved the miner's life and made it possible for him to walk again, and yet the patient, whose heart should have been filled with gratitude because he lived and could walk, nourished a grudge against his benefactor because he was forced to go about with the aid of a cane. His conception of the doctor's duty was that he should have performed a miracle and have given him exactly as good a back as he had before his injury. A few days ago, this patient hobbled into the office of Dr. Moore and complained that his back pained him. The surgeon, ever ready to be of such assistance as he could, told the miner that he would be glad to take him in his automobile to the hospital for an X-ray. They boarded the surgeon's machine and about four miles from Indiana, Pennsylvania, the automobile left the road and overturned. It was believed at first that Dr. Moore had lost control. Farmers rushed to the scene, and when they arrived, found that the doctor had been shot three times in the head, the shots entering his skull from the rear. In the back seat they found the miner with three bullets in his temple and a pistol by his side. The surgeon was dead, and one hour later, without making any statement, the miner died also. A Coroner's jury returned a verdict of murder and suicide.

Fortunately, few doctors are murdered by their patients, but an assault made upon their good name by means of a malpractice action is an incident likely to arise out of any professional relationship, especially where the patient is ignorant. An understanding of these things caused your officers to inaugurate for your benefit the State Society's group plan.

## COLLES FRACTURE—SLIGHT DEFORMITY

On January 6th a physician was called to attend a woman of about fifty years of age. On examination he found her suffering from a Colles fracture of the left wrist. At this time he told the patient that he would not put the fracture up alone but desired another physician to assist him. The patient was taken to her home and the defendant, assisted by another physician who administered an anaesthesia, reduced the fracture and put on splints and the usual dressings. He called on her on the following day, examined the arm but did not disturb the dressings or splints. On January 11th when he called the patient was ill with influenza. He continued to treat her for this condition and also the arm until the 23rd of January. Thereafter he made frequent calls upon the patient, making necessary examinations of the arm until February 21st. On March 1st the patient visited the defendant at his office. He found the arm in good condition. When he was first called to attend the plaintiff he advised her that an X-ray should be taken. The patient stated that she did not want any. On February 6th, on examining the arm the defendant observed a slight deformity which he endeavored to overcome and advised the patient to carry her arm in a sling, which, however, she refused to do. She likewise refused to follow the advice to use the hand and arm. She continued to call on the defendant at his office until April 8th, upon which day she then went to another physician for X-ray. This physician advised the defendant that X-rays had been taken of the patient's wrist and that the patient was dissatisfied and refused to have anything more to do with the defendant.

At the office of the roentgenologist, defendant examined the X-rays and saw that the fractured end of the radius had slipped in around the ulna

just enough to make a deformity and limit the motion a little.

In an action instituted against this physician to recover damages for the bad result, the plaintiff charged that she sustained an injury to her arm by falling upon the sidewalk and that the defendant physician was engaged to attend her for her injury, that he made an examination and found the bones broken and advised that immediate action be taken to set the same, that he removed the plaintiff to her home and called in a physician to assist him in administering an anaesthetic while he performed the necessary treatment for the reduction of the fracture. It is claimed that the defendant stated after making his examination that it was a clean fracture, without splinters or a crushing of the bones and that as a result the hand would be all right after a few weeks, that the plaintiff relied upon the skill of the defendant and his representations that he was qualified to properly attend and care for her, that he was negligent and careless in the setting of the fractured bone and did not use the proper care or attention or appliances in his treatment of the plaintiff, and that by reason of his negligence she was caused to suffer great pain and anguish, the hand became greatly swollen and diseased, the bones allowed to overlap and were not properly united, and that they became disunited, rendering her hand and arm practically useless, and leaving her unable to perform any kind of labor or to move or use the arm without great pain.

When this action finally came on for trial, plaintiff's attorney then being engaged in practice more lucrative than the prosecution of malpractice actions and being pressed to trial, the complaint was dismissed, judgment being entered in favor of the defendant.

---

## MALPRACTICE COUNTERCLAIM

A physician, in an attempt to collect for his services, rendered to a patient instituted an action. As often happens he was met with a counterclaim of alleged malpractice, it being claimed by the patient that he was injured and damaged when he called at the physician's office and that in spite of his weakened and ill condition he was negligently and improperly directed to strip and remove all of his clothing and lie entirely nude upon a cold stone or marble seat or platform which, because of his weakened condition, his advanced age and the low temperature of the physician's office, caused the patient to contract a severe cold which aggravated his illness and retarded his recovery.

The physician was a roentgenologist and the patient had been referred to him by the pa-

tient's family physician, who was treating him for gastro intestinal and gall bladder trouble. On the 23rd, 24th and 25th days of January, the physician as such roentgenologist took a series of X-rays of the esophagus, stomach, small intestines, large intestines, gall bladder and vermiform appendix of the patient. The series consisted of twenty plates. The roentgenologist also made a fluoroscopic examination of the patient's heart and lungs and consulted with the patient's attending physician with reference to the radiographic and fluoroscopic findings.

The matter was finally adjusted by the physician reducing the amount of his bill and the patient withdrawing the malpractice counterclaim.

# NEWS NOTES

## A CANCER CURE

The following letter was received by the State Department of Health While it would have enlivened the pages of Health News, it will be equally interesting to those who read the official organ of the State Medical Society

While the writer would be condemned by judges and juries on account of his illiteracy, he probably has as much knowledge of medicine as the city chiropractor who sports a decorated office and enjoys immunity from prosecution on account of his outward show of eloquence—  
EDITORIAL NOTE

"Sir I writin you in regard to my cancer cure I had an attorney to write for me and never red the last and you have never answered I will write you myself now I have no edication I no nothing about meadison all I have is Mother Wit but I have got a cure for cancer I am cureing them right along I can send you names of as many as you want to write to and let them tell you what I have doen for them after the meadical Doctor faild I take them and cure them now I cure Ezema after the Drs say they can be nothing doen for them now this meadison I go to the woods and get it all and make it at home I go to the Drug store for nothing that goes in it now as for the cause of cancer the only cause I no for it is a bruse for all I have treated in talking to them about them I find they come

from a bruse when they come in the mouth they said it was wheare they bit with theare teeth in 2 cases where they cut a mole on the face in shaving that is as well as I can explaine myself but my meadison wil cure them all of course they can go to fars but I have takin them out with one application as larg as the palm of my hand I tak them off the eye and the meadison gets in on the eye ball and it doesent affect the eye at all it doesent affect the sound flesh at all well as I cant write much I will wind up by saying if you think enough about my meadison if you will send a man heare to see these cures I have cured and talk to them and learn for you what I have doen and see me treat one and see the meadison work there is lots of them heare and I cant see half of them in Ala I want the public to get the benefit of this Great Meadison I am now treating a case of Tuberculosis and he says I am doing him more good than all the Hospitle, and he has been sent to 5 Hospitles by the Government if I had the edication I could do more than every Hospitle in the world if this appeals to you let me heare from you soon as I am thinking of going to Mumphis I will close yours truly

D L McE

Ala

## GENESEE COUNTY MEDICAL SOCIETY

Twelve of the twenty-nine members of the Genesee County Medical Society were present at a meeting in the Holland Club Wednesday afternoon, July 13th

The Society listened to a report by a spécial committee appointed to report upon the request made by the Grange for a solution of the problem for better medical service in rural districts Last winter newspapers widely reported that a child had died in a family residing a short distance out of Batavia, because of lack of medical attention The committee's report showed that this charge was unjust, the child, according to the health officer's report, died of laryngismus, acute attacks of which it had had previously Physicians had been called several times by the parents when the child was suffering with one of its spasms, but they were of short duration, and usually the child had entirely recovered by the time the physician arrived It was because of this that one physician, called on that particular night to

substitute for the physician who had been attending the child, who was out of town, recommended certain procedures to the mother, which were followed and the child recovered, took nourishment and apparently fell into a normal sleep It must have been attacked by another spasm during this sleep, from which it succumbed

The committee reported only in outline and it was suggested that before a final report be given, an effort should be made to have a joint conference with the committee representing the Grange. This suggestion was favorably received and an effort will be made to arrange for a joint conference at an early date

Dr Sadler, President of the Medical Society of the State of New York, discussed the importance of developing the practice of preventive medicine He called attention to the great benefits that are resulting from the anti-diphtheria campaign which the State Society inaugurated less than two years ago He urged the adoption

of programs that would promote periodic examination of the apparently well, especially adults. He called attention to the assistance that the County Society might get from the State Society in developing such programs, particularly from the standing Committees on Medical Economics, Public Health and Medical Education, and the special committee engaged upon the study of diseases of the heart.

Dr W W Britt, Chairman of the State Committee on Economics, supported Dr Sadlier's suggestion for developing the practice of preventive medicine, and offered the assistance of

his committee. He also called attention to the fact that his committee is cooperating with the committee appointed a year ago by the legislature to make a special study of the workmen's compensation laws, and urged the members of the Society to keep in touch with the progress that is being made by this committee in its efforts to reorganize the workmen's compensation law. He told of the investigation the committee had recently made in Syracuse, where an examiner was referring cases for physiotherapy treatment to a group in which he had a peculiar interest. He was convicted of the charge and dismissed as an examiner.

---

### SARATOGA COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Saratoga County Medical Society was held at Rileys Lake House, Saratoga Springs, N Y, Friday, May 27, 1927, at 4 p m.

The application of Dr Howard Johnson, Corinth, N Y, having been received and passed by board of censors, was presented. Motion was made and seconded that he be declared elected a member of our society. Carried.

Motion made and seconded that an invitation be extended to the New York State Medical Society to hold the next annual meeting at Saratoga Springs. Carried.

Dr Carl Comstock, as delegate to the State Society meeting at Niagara Falls, made a few remarks concerning the meeting.

Dr F Eaton gave a brief explanation of the object of the Pre-Natal Clinic being held at the Saratoga Hospital.

Dr Van Der Bogart, of Schenectady, gave an interesting discussion on "Feeding in Infancy."

Following the business and scientific program, a luncheon was served.

R B Post, *Secretary*

---

### ONEIDA COUNTY MEDICAL SOCIETY

The Medical Society of the County of Oneida held its annual outing at Three Island House, Newport, on Tuesday, July 12th.

Among the committee reports heard by the Society was one of a special committee appointed to investigate sites for a tuberculosis hospital. The committee, composed of sixteen members, had made a very searching inspection of all sites mentioned, and many other places that, to them, appeared in certain ways to be suitable for the location of a tuberculosis hospital. A majority of the committee, eleven, reported the advantages and disadvantages of the many sites that they had visited, and finally decided upon a location at Alder Creek, in the northeastern part of the county. This location, they stated, has all of the advantages of every other location that was mentioned. The only disadvantage mentioned by any who had seen the place is its distance from Utica, but the committee reported that this, in their opinion, is not a disadvantage, that the distance is not so great but that consultants could readily reach the hospital, and the facilities for keeping

open roads in the winter are such that the hospital would be accessible the year round. A minority, three members of the committee, reported in favor of a location closer to Utica, whose only advantage they named was proximity to Utica.

The members discussed both reports freely and the President called upon all physicians who would be expected to have ideas upon the matter, to give their opinion to the Society. The Society finally voted unanimously in favor of the site selected by the majority of the committee. Before selecting this location, due consideration was given to the report made by Jamieson Marshall, of the National Tuberculosis Association, who favored the site closer to Utica.

Dr Sadlier, President of the Medical Society of the State of New York, outlined the activities of the State Society and particularly stressed the importance of developing the practice of preventive medicine which, he said, differs from curative medicine only chronologically. He cited the great advantages that are accruing from the

anti-diphtheria campaign which the State Society has sponsored, and forecast an equally encouraging result from a more active campaign in periodic medical examinations. He commended the Society for its interest in securing a location for the tuberculosis hospital and stressed the importance of medical men, through their organization, taking a greater interest in community affairs. A Committee on Public Relations, he said, should be one of the most important committees in every County Society, for upon it will

devolve the duty of coordinating the public welfare agencies and the medical men in effective community service. He also commended the Society for the enthusiasm shown in bringing post-graduate facilities to its members and urged its further cooperation with the Committee on Public Health and Medical Education.

Dr Post announced that the next annual meeting of the Fifth District Branch will be held in Syracuse on October 13th, and requested a full attendance from Oneida County.

### GREENE COUNTY MEDICAL SOCIETY

The Medical Society of the County of Greene held its summer meeting in Greenville on Tuesday, July 19, 1927. The guests were Dr Sadlier, Dr Lawrence, Dr Borst, of Poughkeepsie, and Dr Huntington Williams, District State Health Officer.

Greene County is a typical rural county, it has two railroads, one on the west border and the other on the east border. The Catskill Mountains extend across the county, dividing it into two sections, so that Catskill, its largest center of population, is accessible only with difficulty to a great portion of the residents of the county. There are, however, splendid automobile roads traversing it in every direction. In summer its population is greatly increased by visitors to the mountain villages and camps and, therefore, summer is the busy season for the physicians. In spite of that fact, nine of the twenty-four members of the Society were present at this meeting. This attendance was even more remarkable because three of the nine men present—Dr Willard, of Catskill, Dr Van Slyke, of Coxsackie, and Dr Wasson, of Greenville—have been in practice respectively fifty-nine, fifty-eight and fifty-five years. The oldest member in the Society is Dr Rouse, of Leeds, who has been in practice sixty years. Dr Van Slyke holds the distinction of having been health officer for a greater continuous length of time than any man in the State. Only 17 per cent of the members of the County Society have been in practice twenty years or less, and another 17 per cent have been in practice more than fifty years. 37 per cent have been in practice more than thirty-five years.

The most important matter of business before the Society was the development of plans

for the cooperation of the County Society with a committee which contemplates building a hospital for Catskill. Some years ago a benevolent citizen donated \$40,000.00 for the erection of a hospital. The sum was not considered adequate at the time, but now the trustees of the fund have decided that the hospital should be built and they contemplate asking the communities to assist in making the fund ample for the erection of a suitable hospital. There is a question in the minds of some of the physicians as to whether there is need for a hospital in the county inasmuch as there are excellent hospitals in neighboring counties and since the mountains so divide the county that residents in one section would very likely continue to use the hospital facilities offered by neighboring counties.

Dr Sadlier, in his address, warmly urged the Society to take an active interest in the organization of the hospital for several reasons, 1st, that it was understood that the committee in charge of the erection of the hospital is composed entirely of laymen, and the County Society, therefore, owes the committee assistance. In the second place, the use of the hospital will devolve upon the physicians of the county, and they should, therefore, offer the construction committee assistance and advice in order that the hospital may give the community the largest amount of service. He suggested that the Society hold an adjourned meeting for the purpose of discussing the hospital plans as far as they are known and, at the same time, prepare suggestions which later they may offer to the construction committee. This was agreed upon, and an adjourned meeting was called for August 2nd in Catskill.

# THE DAILY PRESS

## HEALTH RULES

Life and health under modern conditions depend on watchfulness and care to an extent as great as in the days of savagery. Rules of health are numerous, and voluminous, and copious, and imperious. They form a chain which is no stronger than its weakest link. One may keep all the health commandments save one, and that one broken will bring disease and death. One may, for example, be careful with eating, drinking, rest, sleep and watchful against accidents, and yet be the innocent victim of milk-borne infection.

How great is the number of necessary health rules is painfully apparent to one who tries to reduce them to a simple code. Benjamin Franklin devised a set of rules for his daily life, but realized that he could not keep all of them all the time. He therefore concentrated on a single rule for each day, and in that way he gradually acquired an unconscious tendency to keep them all. Some such plan will apply equally well to the keeping of rules of health.

Heat and humidity bring great discomforts and indirectly produce disease and death, though not to the extent of former days when the causes of fermentation and infection were not understood. Rules for the care of health during hot weather have frequently appeared in periodicals and the daily press. The following rules were issued by the New York Tuberculosis and Health Association, and were printed on July 19, in the New York *Herald Tribune*.

Drink plenty of plain water—cool but not ice cold.

Eat light, wholesome foods, plenty of vegetables, little meat, but do not eat cold food only.

Bathe frequently.

Avoid undue or unaccustomed physical exertion.

Don't worry about the heat.

The last suggestion may sound trite or even humorous, but it isn't. It is important and it is possible.

For summer vacationists, a few hints from the New Haven Department of Health are splendid.

Out of doors. As many hours a day as possible.

Sunburn. Get it a little at a time.

Exercise. Plenty of it, but start gradually.

Swimming. Always have some one with you.

Sleep. Catch up on the past and stock up for the future.

Appetite. Don't overeat.

Water. If in doubt, boil it.

Milk. Pasteurized is safest.

Green vegetables. Have them thoroughly cleaned.

Poison ivy. Has ruined many a vacation. Keep away from it.

Mosquitoes. It is better to screen than scratch.

Good health conditions are a great help in conquering tuberculosis and hot weather precautions are of high value. The information service of this association will be glad to give any further information desired, without charge, to all who may inquire.

## ADULT EDUCATION

The assertion has often been made, even by expert psychologists, that men and women get few new ideas after the age of twenty-five. But the New York *Times* of August 7th discusses the subject editorially and quotes authorities to show that adults can learn as readily as young persons. The editorial says:

"A booklet issued by the American Library Association is filled with such a variety of proofs that adults can learn, and moreover that they are eager to do so, that enthusiasm about the possibilities brims over. One of the most interesting reports is that of Professor E. L. Thorn-

dike of Teachers College, Columbia University. During the past two years he has conducted experiments with two groups, one averaging in age 42, the other 22. Both were compared with a group of children. The adults were taught to write with the wrong hand, to operate the typewriter, and there were classes in algebra, science, foreign languages, etc. For all three groups there were classes in reading, spelling, arithmetic and other elementary school subjects. In general, both adult groups learned more rapidly than the children. The older group of adults learned almost as rapidly as the younger—roughly,

about five-sixths as fast. The conclusion is that ability to learn increases until about 20, when it remains stationary for a time, and then declines very gradually. No one under 50 should be deterred from trying to learn something new by the fear of being too old, and even after 50 the decline is so slow that the attempt to learn is still well worth while.

"Not lack of ability, but lack of opportunity or desire to learn, now appears to be the reasonable explanation why adults so seldom learn a new language or a new trade. Both opportunity and desire have greatly increased everywhere in this country in recent years. Which one causes the other, if they are cause and effect, cannot be decided, so closely have they moved together along a rising plane. Correspondence schools are a part of the general development."

The editorial quotes descriptions of rural librarians in answering calls for literature and

refers especially to a letter from a homesteader's wife in the mountains of Montana who received books by parcel post. The closing words of the editorial are:

"It is a long letter, with accounts of neighbors who have come ten or fifteen miles to 'study the book on precious stones and minerals,' or 'to study the Alpine flower book,' preparatory to identifying the flora of the near-by glacier. The entire letter, like the entire subject of adult education, may be drawn to a point in one sentence of hers—'It is to renew one's youth'."

The editorial reflects the opinion of the leaders of the Medical Society of the State of New York, that practicing physicians can learn as readily as young medical students. The State Medical Society acts on that opinion and provides courses in medical study for physicians of all ages. It seems strange that anyone should deny that adults can learn readily.

### BEAUTY DOCTORING

Dr. Cadman answers the following question in his daily department in the New York *Herald-Tribune* of January 14th:

"My wife, who is fifty years old, proposes to have her face lifted. What do you say about such a proposal?"

Dr. Cadman's answer was as follows:

"So far as your wife is concerned, absolutely nothing. I have not seen her face. But since she lives behind it and you live in front of it, you ought to have some rights in the matter."

"Perhaps she may heed the warning that the operations of professional beautifiers are not uniformly successful. Nevertheless, physical wonders have been wrought for some faces, and if she decided upon the venture, may success attend it!"

"Of course, you both know that real loveliness

is of the soul and can find its replica in any countenance, however old or wrinkled. Indeed, it has a knack of lighting up the human face with a radiance which obliterates age, weariness, sorrow, as well as physical defects."

It is unfortunate that the eminent preacher should even seem to approve the work of beauty doctors. He was probably thinking of bone grafting and the formation of tissue flaps for the cure of deformities which the operation could not make worse. But the situation is very different when scars are produced for the cure of double chins, and paraffin is injected into the skin with the intention of supplying missing fat. The end result of the injections after four or five years is a hideous fibrosis with contractures and even the development of malignant disease. Such a condition as this is the concern of the patient's whole family and of the public.

### THE IDENTIFICATION OF BULLETS

As this JOURNAL goes to press the whole world is discussing the cases of Sacco and Vanzetti, who are under sentence of death in Massachusetts for murder. The Communists are demanding the release of the men on the ground that their guilt has not been proved. The trial of the men took place about seven years ago and every legal means has been used to secure the freedom of the accused. Since the trial occurred, a means of identifying bullets has been developed. This new method is described by Major Calvin H. Goddard, Associate Director of the Bureau of Forensic Ballistics of New York City, in an illustrated article on page 701 of this JOURNAL of August 15,

1926. It is based on the principle that each individual pistol will produce the same scoring on every bullet that is fired from it, and these scorings are as constant and evident as the lines of a person's finger print.

The *New York Times* of August 10, describes the tests by which Major Goddard has recently demonstrated that two bullets taken from the body of the murdered person were fired from a pistol that was in the possession of one of the accused men.

Since physicians are often called to do autopsies on murdered persons, they will find Major Goddard's article of great practical value.

# BOOK REVIEWS

**THE DISEASES OF INFANTS AND CHILDREN** By J P Crozer Griffith, M.D., and A. Graeme Mitchell, M.D. 2nd Edition, reset. Two octavo volumes totaling 1715 pages, with 461 illustrations, including 20 plates Philadelphia and London, W B Saunders Company, 1927 Cloth, \$20.00 net.

This two volume *Diseases of Infants and Children* is a scholarly work, with more than the average number of references to the medical literature. It is well written and well printed on good paper with illustrations above the average in clearness.

The weight and height tables of the Children's Bureau have been selected for boys and girls up to 6 years, and Wood's tables for weight and height have been selected for boys and girls 5-18 years. Height and weight statistics are largely a matter of preference and the tables selected are probably as satisfactory as any. Certainly they have the merit of nearly universal use.

Among the subjects, the treatment of which is to be commended, are Premature Infants, Scarlet Fever, Scurvy, Pyloric Stenosis, Meningitis, Eczema, Otitis, and Diseases of the Blood, Spleen, and Lymphatic Glands.

In dealing with the feeding of the premature, one wishes the authors had been more definite and given us the results of their personal experience in addition to the general principles. This same want of personal preference comes out in various places in the book, another instance being the lack of comment on personal experience with Scarlet Fever Streptococcus Antitoxin. With the large experience of the authors at their command, the reviewer feels this lack of record of personal opinion to be a great loss.

Another lack is in the artificial feeding of the new born and young infant, which the reviewer thinks might have been more helpful if worked out in more detail as it is for the older child.

However, the points just mentioned cannot detract from the real value of the book for reference, and for an every day guide, which is the real field it covers, and the appeal of the book will be, in the future as it has been in the past, to the student, the pediatricist and the general practitioner. It is highly recommended.

ARCHIBALD D SMITH

**MANAGEMENT OF THE SICK INFANT** By Langley Porter, B.S., M.D., and William E. Carter, M.D. 3rd Edition, revised. Octavo of 726 pages, illustrated. St. Louis, The C. V. Mosby Company, 1927. Cloth, \$8.50.

The writers of this book were prompted to write it because of the long felt need of a single volume dealing with the treatment of diseases as manifested in infancy.

The first part of the text is very sensibly devoted to the consideration of symptoms and their significance, such as vomiting, diarrhea, constipation, nutrition, hemorrhage, pain and tenderness, convulsions, fever, and cough. The second part deals with diseases of the various tracts and regions, as well as with infectious diseases and internal secretions. The third and last section is devoted to methods, formulas, recipes, and drugs. The last section is the only one that is illustrated, and this is quite appropriate since the descriptions of the clinical procedures require good illustrations, not only to simplify the description, but also to save a considerable amount of space on the printed page, and this is of value in keeping the book within the handy size.

The authors are men widely known, not only on the Pacific coast where they have carried on pediatric work, but throughout the country, and their language is always clear and concise. Their methods are simple, although scientific, and the present edition which is the third is of about the same size and arrangement as the

previous ones. It will be welcomed by those who feel the need of a practical working guide in the difficult task of treating sick children.

WM HENRY DONNELLY

**THE PRACTICAL MEDICINE SERIES** Comprising Eight Volumes on the Year's Progress in Medicine and Surgery Under the General Editorial Charge of CHARLES L. MIX, A.M., M.D. Series, 1926. Chicago, The Year Book Publishers, 1926. General Surgery. Edited by EVARTS A. GRAHAM, A.B., M.D. 12mo of 726 pages, illustrated. Cloth, \$3.00. Price of the series of eight volumes, \$15.00.

This book of abstracts on general surgery has been a part of the yearly library acquisition of the general surgeon for so long that it needs no introduction.

Dr. Graham has used essentially the same abstracting technique as that employed by his predecessor the late Dr. Albert Ochsner. This is probably due to the fact that preparation of the abstracts is still under the direction of Dr. Louis J. Mitchell.

This particular volume contains many interesting abstracts particularly on the gall bladder, treatment of burns, and diseases of the breast. As a whole, this volume is essentially as complete and useful as those of previous years.

HERBERT T. WIKLE

**URINARY SURGERY** A Handbook for the General Practitioner. By WILLIAM KNOX IRWIN, M.D. 2nd Edition, revised and enlarged. 12mo of 271 pages. New York, William Wood and Company, 1927. Cloth, \$4.00.

This brief work covers the subject of Urology in a clear and concise manner. It is in no sense a reference book, but intended as a guide for the busy general practitioner.

The first chapter is an excellent review of the surgical anatomy and anomalies of the urinary tract.

Each of seven chapters is devoted to a symptom, in which all possible lesions producing that symptom are discussed, e.g., frequency, retention, incontinence, etc. This helps the practitioner to visualize the possible or probable etiology in a given case, and to properly institute early and suitable methods of investigation.

We note that the writer regards the lithotomy position as quite unnecessary for cystoscopic procedures. The author also has a novel way of sealing the male urethral meatus in temporary urinary incontinence cases.

The description of operative technique covers the entire urinary tract.

AUGUSTUS HARRIS

**INTERPRETERS OF NATURE.** Essays by SIR GEORGE NEWMAN, K.C.B., M.D. Octavo of 296 pages. London, Faber and Gwyer, [1927]. Cloth, 12s. 6d. net.

Sir George Newman's book of a scant 273 pages will satisfy many tastes. It will appeal to the student of medical history, warm the heart of the intelligent who are drawn to interesting things well done by a master hand at stringing words into sentences, and to the individual who merely asks to be entertained. A book every physician should keep on his reading table and read and reread.

**INTERPRETERS OF NATURE** is composed of nine essays of men whose careers, in science or literature, are identified with the progress of medicine. The book opens with *The Great Paduans*. A Century of Medicine at Padua. The second essay concerns itself with Thomas Sydenham, Reformer of English Medicine. There follows delightful sketches of Herman Boerhaave, John Hunter, the private practitioner as pioneer in preventive medicine, John Keats, apothecary and poet, Louis Pas-

teur, William Osler, a physician of two continents, Modern Interpreters, and the last one, Future Interpreters, everyman in preventive medicine

Besides reading like a novel it has the stamp of authority, is well indexed, and a book one just has to urge one to acquire and enjoy

T S W

**EXAMINATION OF CHILDREN BY CLINICAL AND LABORATORY METHODS** By ABRAHAM LEVINSON, B.S., M.D. 2nd Edition Octavo of 192 pages with 85 illustrations St. Louis, The C V Mosby Company, 1927 Cloth, \$3 50

Physicians almost invariably become expert along one or two lines, clinical ability or laboratory skill Dr Levinson is a fine example of a man who is expert both as a clinical pediatrician and as a laboratory expert.

The present volume is the second edition of a work which appeared in 1924 and which was received with open arms by all those interested in the medical care of children As will be recalled by readers of the first edition, Dr Levinson gave a course in laboratory work to the students at the Northwestern University Medical School, and he has based this treatise upon it The original outline has been followed in the second edition, and consists of three main divisions, first Methods of clinical procedures in infants and children Secondly, a description of simple laboratory tests that can be carried out in the ordinary laboratory or office. Thirdly, a discussion of the interpretations of various clinical laboratory tests as applied to infants and children

Emphasis is very properly laid on the difference between the normal standards in children and those in adults This book was not written for the children's specialist nor for the laboratory worker, but for the medical student and the general practitioner In this second edition several methods of examination have been elaborated upon, and a few new methods added

Chapters on Case History and Physical Examination have been enlarged, and sample charts are presented with the hope of supplying a working guide for the busy practitioner It would seem to me that this book is almost indispensable to any physician who treats children either as an exclusive line of work, or as a part of his general practice.

WM HENRY DONNELLY

**PRACTICAL GASTROSCOPY** By JEAN RACHET, M.D. Authorized translation by FRED F IMIANTOFF, D.S.C., B.A. Octavo of 148 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$5 50

This little book by William Wood and Co is attractively assembled and profusely illustrated, including some beautiful plates of intra-gastric views The subject matter includes a detailed resumé of the history of the gastroscope followed by a discussion of the advantages of the rigid over the flexible and the straight over the elbowed instruments The author believes Dr Bensaude's instrument superior because it is introduced over a filament guide with a metal tip Otherwise it differs very little from others in use such as the Schindler and the Sternberg gastroscopes

Although rejecting some of Schindler's doctrines his dicta concerning position of the patient, introduction of the instrument and orientation in the stomach are ultimately adopted

An elaborate study of the hardened cadaver placed in the various positions used for gastroscopy and sectioned was made to determine the position of the organs in these positions and to find the best position for examination This led to the conclusion that a new position called dorso-lumbar lordosis is the ideal one for examination In actual practice on the living subject however this was contradicted and the admission finally made that the genu-cubital and left lateral positions, held by other authors to be superior were the most satisfactory

Much zeal and labor were necessary to make the investigations described and the author deserves great credit therefor Although little has been added to the

knowledge of gastroscopy as developed by Elsner, Schindler and Sternberg, the book presents in a general way a readable discussion for gastroscopists and others especially interested in gastric examinations

HENRY F KRAMER

**SOCIAL FACTORS IN MEDICAL PROGRESS** By BERNHARD J STERN, Ph.D. Octavo of 136 pages New York, Columbia University Press, 1927 Cloth, \$2 25

It struck the reviewer as unfortunate this short work was not offered to the reading world by some publishing house of popular fiction, accompanied by all the fan-fare and ballyhoo and publicity given by such publishers to their product, instead of slipping without fuss or noise upon the book-lists which, at best, are studied only by the select few who are called by the man on the street "high-brows"

Doctor Stern has written a readable, instructive, interesting book And what more can one say or what higher praise can one give to an author or his work?

**SOCIAL FACTORS IN MEDICAL PROGRESS** is done in two parts Part One deals with such delightful subjects as, Factors which Retard the Diffusion of Innovations, Conservatism in Medicine, Opposition to Dissection, Opposition to Harvey's Theory of the Circulation of the Blood, Reception of Auenbrugger's Theory of Percussion, Opposition to Vaccination, Opposition to Holmes and Semmelweis, Opposition to Pasteur and His Discoveries, Opposition to the Doctrine of Antisepsis, Opposition to Asepsis, and a Summary

Part Two deals with a Biography in Medical History, The Dependence of a Discovery upon the Existing Knowledge, and Multiple Inventions and Discoveries in the History of Medicine.

Then follows a complete Bibliography and Index.

T S W

**THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioner's Index** Forty-fifth Year Octavo of 560 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$6 00

The present is the forty-fifth consecutive yearly volume of the Medical Annual, and it is the pride of the publishers that it has not yet ceased growing As in previous issues an attempt has been made to give a synopsis of the work done, and the publications which have appeared, during the year

A feature which is unusual in a work of this kind, is the presence of really remarkable illustrations in the form of photographs, colored plates, and diagrammatic drawings While the contributors are all from the British Isles, it must be said that the American literature receives the largest share of consideration There can be no question, but that works of this character are of great value to the busy practitioner, and it is for him especially, that this book is intended The International Medical Annual continues to hold a reserved place in the front ranks of the year books of medicine

WM HENRY DONNELLY

**LES STUPÉFIANTS** Par le Docteur R. PORAK 12mo of 348 pages, illustrated Paris, Gaston Doin & Cie, 1927 Paper, 18 Francs

The author has lived since 1918 in Persia, China, and South America, where he has been able to observe the effects of narcotics in these various regions If alcohol and its action has been studied extensively in Europe, other poisons such as opium, hasheesh, and cocaine, have been neglected both by doctors and physiologists This gap, Porak in his book, has attempted to bridge. The writer is a physiologist as well as a clinical worker and is well known for his article on "The New Investigations of Diuresis" and he applies in this instance his individual and original methods to the pharmacodynamics of the narcotics

An interesting feature of the book is the setting forth

of a number of personal experiences of intelligent patients with the various drugs

WM HENRY DONNELLA

**THE FIFTH AVENUE HOSPITAL CLINICS First Series**  
Based on the Material from the Semi-Monthly Staff Meetings, 1925 By the Editorial Board Octavo of 336 pages, illustrated New York, Paul B Hoeber, Inc., 1927 Cloth, \$5 00

This volume is composed of material from the semi-monthly staff meetings of the Fifth Avenue Hospital, together with cases in the hospital. The articles are arranged chronologically in the order in which they were presented at the various staff meetings. They are of a very high order, and the selection of a few therefrom naturally depends upon the individual interests of the reviewer. The articles which appeared in the present instance are

CERVICAL ADENITIS—By R. Franklin Carter

ROENTGENOGRAMS OF PULMONARY TUBERCULOSIS—By Lewis Gregory Cole.

CONVULSIONS IN INFANCY—By Frederic H. Bartlett.

It would seem that this custom of giving to the public, in a well printed, well bound, and well illustrated volume, the interesting articles read at the staff meetings is a good one, and might be followed with advantage by other institutions

W H D

**HISTORY OF MEDICINE.** By DR MAX NEUBURGER.  
Translated by ERNEST PLAYFAIR M.B., M.R.C.P. in two volumes Vol. 2, Part 1 Octavo of 135 pages London, Humphrey Milford, New York, Oxford University Press, 1925 Paper, \$2.25 (Oxford Medical Publications)

This is a volume of 132 pages of delightful English, full of reliable medical history, touching six important phases of the subject i.e., Medicine in the Early Middle Ages, Medicine in the Eleventh and Twelfth Centuries, Arabic Influence upon Western Medicine, Medicine in the Thirteenth Century, Medicine in the Later Middle Ages, Historical Survey of Literature

For a non German reader this is a valuable library contribution, especially as the original comes from the pen of a scholar such as Neuburger. The style is easy and fluent. Indeed on taking up the book, one finds it difficult to put it down, until the last page has been read, and, having accomplished the whole, there remains a sense of regret that there is not more of it.

J M VAN COTT

**MUSCULAR ACTIVITY** By ARCHIBALD VIVIAN HILL, M.A., Sc.D., F.R.S. Octavo of 115 pages, with illustrations Baltimore, Williams and Wilkins Company 1926 Cloth, \$2.75

Those who are interested in the physiology of muscle will welcome this little book which is a report of the sixteenth course of the Herter Foundation lectures. If it contained no more than a mere summary of the contributions of the author and his co-workers to the subject its publication would be fully justified, but, far more than that, it is a series of sharply focussed discussions, in the light of recent research generally, of certain aspects of the mechanical, chemical and thermal phenomena of muscle-response and of the factors and processes concerned in recovery after vigorous muscular exercise.

The vividness of presentation throughout reflects the spirit of present-day scientific activity in the field under discussion, contributes to the attractiveness of the book and gives one the impression that the lectures have been printed as actually delivered, without fussy revision. This very commendable characteristic invites, indeed almost demands concentration of attention on the part of the reader lest he miss, here and there, some well-

taken point in evidence or accept as firmly established some still doubtful conclusion.

Apparently, the lectures were intended for an audience composed mainly of those who are somewhat familiar, not merely with modern but also with recent physiology, and as such they are really brilliant and stimulating, carrying one far beyond the best of textbooks and furnishing very useful, though brief bibliographic lists for checking-off purposes and for the enlightenment of anyone who, being interested, may not be sufficiently familiar with the specified results of recent research.

Progressive practitioners of medicine will find much of value in the book, especially in the fourth lecture, which deals, in a broad yet incisive way, with recovery processes and pointedly suggests some applications of this newer knowledge to conditions of fatigue and exhaustion.

J C. C.

**CAVERNOUS SINUS THROMBOPHLEBITIS and Allied Septic and Traumatic Lesions of the Basal Venous Sinuses** By Wells P. Eagleton, M.D. 12 mo of 196 pages, illustrated New York, Macmillan Company, 1926

The introduction of the inductive method of reasoning made education real and living. Modern scientific pedagogy requires that the laboratory method be used in its widest application.

The author of this study has taken the history of twenty-five personally observed cases of cavernous sinus thrombophlebitis and reported them for definite objects. These objects are the recognition that the lesion must be regarded as a group of diseases, that exophthalmus chemism may or may not be present and that drainage plus arterial ligation is required for the rest of the part.

The text is an exhaustive treatise on the various types of this relatively rare but serious pathological condition.

R. F. BARBER.

**HYDROGEN ION CONCENTRATION Its Significance in the Biological Sciences and Methods for Its Determinations** By Leonor Michaelis, M.D. Volume I Principles of the Theory Octavo of 295 pages with illustrations Baltimore, The Williams & Wilkins Co., 1926 Cloth, \$5 00

This is by no means an elementary book. The author presupposes a certain amount of training in physical chemistry as well as in mathematics. This book also demands time and close attention, but given a student with the necessary previous training, he will be well rewarded for the time and attention that he may bestow upon this work.

The author is a master in this field and his presentation of the subject clearly shows it.

The translator is to be congratulated on the excellence with which he performed his part of the undertaking.

The original edition in German was published in 1921, but Prof. Michaelis revised this work before it was translated into English, so that it is more than an English translation of the second edition. It is really almost a third edition published in English in 1926.

BENJAMIN DAVIDSON

**HISTORY TAKING AND RECORDING** By JAMES A. CORSCADEV, M.D. 12mo of 78 pages New York, Paul B Hoeber, Inc., 1926 Cloth, \$1 50

This book of seventy-three pages is worth the reading by the practitioner as well as the student of medicine.

The importance of careful history taking, as an aid in diagnosis and treatment, is made clear.

Chapters on principles of taking and recording histories, symptoms, list of terms employed in history taking, lists of symptoms and analysis of symptoms serve to render one's history taking a more orderly and complete procedure.

JOSEPH G. TERRENCE

# OUR NEIGHBORS

## HUMAN RABIES

A case of Human Rabies, in which the diagnosis was confirmed by animal inoculations, is described in the June issue of the Journal of the Tennessee State Medical Association by Drs Wood, Yarberry and Litterer

A laborer, aged 26, living in Knoxville, was bitten by a strange dog on the left index finger. The wound was treated by a physician, and was healed in about three weeks

About two months after the bite, the finger began to show pain which extended up the arm and shoulder. In four or five days twitching of the left hand and arm began, and he was unable to swallow. He became restless and excited, and his mouth filled with foamy sputum. The contractions involved the entire left side, and cyanosis developed. Death occurred two days after the severe symptoms began.

An autopsy was done on the head only. There was no evidence of acute inflammatory changes in the meninges or the surface of the brain. There was no excess fluid on the ventricles, but throughout the brain there were many punctuate hemorrhagic areas.

Sections of the brain revealed a few minute bodies resembling Negri bodies which were

smaller and stained less intensively than those in animals.

Sections of the hippocampus major were injected into three guinea pigs and one dog in the Knoxville Branch of the State Laboratory, all of which died from the 19th to the 23rd day after inoculation.

Specimens sent to the State Laboratory in Nashville were inoculated into three guinea pigs and two rabbits, all of which died from the 20th to the 24th day, and all showed numerous Negri bodies. The report continues:

"From the first series of rabbits that died of rabies, inoculations were made into a second series. These rabbits developed rabies on an average of eighteen days.

"The second series of rabid rabbits were inoculated into a third series. The third series came down with the disease in fifteen days.

"Up to the present time, there have been seven series inoculated. All have died of typical symptoms of rabies and the Negri bodies demonstrated in the entire series.

"The last inoculated series died in eleven days.

"Further inoculations will be made with a view to produce a 'fixed virus' similar to the one used by the various Pasteur Institutes."

## DRUNKENNESS DIAGNOSED BY CHEMICAL TEST

This JOURNAL of June 1st commented editorially on a new test for drunkenness that had been reported in the daily papers which printed news of the Washington meeting of the American Medical Association. The author of the article read before the A. M. A. was Dr Emil Bogen, of Los Angeles, who has a similar article in the June issue of California and Western Medicine. This article is entitled "The Diagnosis of Drunkenness—A Quantitative Study of Acute Alcohol Intoxication." It correlates the concentration of alcohol in the excretions with the data secured by the clinical and neurological examination of one hundred persons suspected of alcoholism brought to the Los Angeles General Hospital. The examination of each patient included the following points:

"1 Direct question as to quantity and variety of liquid imbibed and time since the last drink

"2 If odor of alcohol is perceptible when patient exhales deeply

"3 Size of the pupils

"4 If the patient's face appears flushed

"5 If patient staggers or reels when he tries to walk unassisted across hallway

"6 If patient can stand with feet together and eyes closed without swaying (Romberg test)

"7 If patient can touch tip of nose with out stretched forefinger with eyes closed (Coordination test)

"8 If patient can speak clearly, without slurring or mixing up syllables (Test phrase 'Methodist Episcopal' was often used)

"9 If any aberration of conduct or behavior was noted, especially garrulousness, boisterousness or pugnacity

"10 If there was any complicating injury or disease present.

"11 Any other information which might be of value

"12 A specimen of urine was obtained on admission and placed in a sealed test tube on ice until examined for alcoholic content. A sample of expired air was taken in a football, and immediately tested for alcoholic content.

"For determining the concentration of alcohol

you can simplify the problem  
of nutrition with this effective  
health-food and digestant!

# Maltine

P L A I N

How often do your patients lag on the road to recovery because of inability to absorb proper nourishment? How many times have you longed for some quick, effective way of building up their strength?

When the delicate digestive processes are weakened or disarranged—when the call is for nourishment, and the system has trouble in absorbing it—Maltine may be tried

Maltine is not only a valuable nutrient in itself, but *an agent for the assimilation of other nutrients*. It contains vitamins, mineral salts, and soluble vegetable albuminoids—all highly important in the growth

of the bodily tissues. And tests show that it contains a high percentage of diastase, the active digestive agent which converts starch into sugar

Maltine is the *only* malt extract which combines in concentrated form the essential proteid elements of barley, wheat and oats. It mixes readily with milk, gruel, and similar foods, making them more palatable. It is always available, always dependable, always pure

As a nutrient, as a digestant—give Maltine, the standard product of a standard house. Every druggist has it

*Rich in diastase*

(Continued from page 932)

in the breath the patient was asked to blow up a football having a capacity of about 2,000 cc. This air, while still warm, was then bubbled at a moderate rate through 5 cc of a hot solution of 0.33 per cent (N/15) potassium dichromate in 50 per cent concentrated sulphuric acid. The color change, from reddish yellow to greenish blue, was then measured by comparison with a series of standards previously made up by the addition of known amounts of alcohol (1, 2, 3, 4, and 5 milligrams) to 5cc of the reagent and sealed.

"For determining the concentration of alcohol in the urine, blood or spinal fluid, 1 cc of the unknown solution (or  $\frac{1}{2}$  cc in some cases) was placed in a test tube and a purified current of air was bubbled through this tube and then passed through 5 cc of the potassium dichromate sulphuric acid mixture as used above for ten minutes, both tubes being immersed in a boiling-water bath. In these tests, in addition to noting the color change by comparison with known standards, as above, the amount of reduction due to the alcohol was determined more accurately by titrating with a solution of N/30 ferrous ammonium sulphate in 5 per cent sulphuric acid, using three drops of a 1 per cent solution of potassium ferricyanide as an indicator, until the deep blue color was obtained. Each 2 cc of the ferrous ammonium sulphate solution less than 10 cc required for this titration represented 1 milligram of alcohol in the unknown solution when 1 cc of the urine, blood or spinal fluid, etc., was used. When acetone was present in the unknown solution, it was removed by the addition of 1 cc of Scott Wilson's reagent before aeration."

The results of the examinations were set forth in seven tables. Commenting on the tables, the author says

"The relationship of the concentration of alcohol in the urine to the degree of intoxication of the subject is strikingly brought out in this table. None of the patients with less than 1 milligram of alcohol per cc of urine were found to be intoxicated, a little more than half of those having from 1 to 2 milligrams per cc were so diagnosed, nearly three-fourths of those having from 2 to 4 milligrams and every individual having 4 milligrams or more per cc of urine were so pronounced. These diagnoses were naturally very conservatively made, since the receiving physician was called to court to sustain his impression in many cases, and unmistakable clinical evidence was insisted upon for this purpose.

"Even more striking is the relationship between the concentration of alcohol in the urine and the different symptoms usually considered indicative of acute alcoholism. The odor of

alcohol was present in less than half of those showing under 1 milligram of alcohol per cc urine, in more than three-fourths of those showing from 1 to 3 milligrams, and in every instance where the urine contained 3 milligrams or more of alcohol per cc. On the other hand, the dilated pupils and flushed face, so frequently called on as evidence, were found in less than one-third of these cases, and were particularly noted in the moderate groups, being replaced by constricted pupils and pallor in a high proportion of those coming in coma or stuporous.

"The inability to stand straight without swaying is generally accepted as a characteristic symptom of acute alcoholism. More than three-fourths of the patients in this series showed this sign, of whom twenty-nine, as noted above, were unable to stand at all. The swaying was noted in less than 20 per cent of those showing under 2 milligrams of alcohol in the urine, but in more than 80 per cent of the others who were able to stand at all. In no case with 3 milligrams or more was the subject able to stand without swaying. Marked incoordination of the hands was recorded in thirty-nine cases, and was most frequently found in those who had more than 3 milligrams per cc. Behavior disturbances, on the other hand, including garrulousness, volubility, euphoria, boisterousness or pugnacity was more pronounced in those showing from 2 to 4 milligrams as they tended to lapse into sluggishness, stupor or coma."

The author continues

"The concentration of alcohol in the urine cannot be taken as an absolute indication of the alcoholic concentration in the patient's tissues because of lack of information as to the time period during which the urine had been secreted, as it would, on the whole, represent the summation of all of the different concentration existing during the period of secretion.

"The concentration of alcohol in the breath offers a very attractive-looking substitute (to urine tests), and table 5 shows it keeps pace with that in the urine."

The results of testing the blood and the spinal fluids are also shown to be similar to those of the urine and breath.

The author says in conclusion

"In view of the difficulty in making the diagnosis of acute alcoholic intoxication from the clinical evidence alone, as may be confirmed from a review of the data in the cases above presented, and in view of the constancy of the findings as to the concentration of alcohol in the urine and in the breath with reference to the degree of alcoholic intoxication, it is concluded that the examination of patients to determine the state of intoxication should in every case include some quantitative determination of the amount of

alcohol present in the urine, breath, or body fluids

"We rely upon the alcoholic concentration in the urine, breath or tissues as the most important single factor in arriving at a correct conclusion as to the degree of intoxication of a patient"

## TULAREMIA

Tularemia is a disease of wild rodents, especially rabbits. It is caused by the bacterium tulareuse, which is named from Tulare County, California, where the disease was first demonstrated in 1911 by McCoy and Chapin. It may be transmitted to man. An article on the human disease, by Dr. C. N. Kavanaugh, is contained in the July issue of Kentucky Medical Journal from which the following abstract is taken—

### EDITOR'S NOTE

Man acquires the disease from the bite of an infected fly or tick, or by contamination of wounds or the conjunctiva by fluids from infected animals. The author says

"Four clinical types are described (1) Ulceroglandular, the primary lesion being a papule later an ulcer of the skin and accompanied by enlargement of the regional lymph glands, (2) Oculoglandular, the primary lesions being a conjunctivitis and accompanied by an enlargement of the regional lymph glands, (3) Glandular without primary lesions but with enlargement of the regional lymph glands, (4) Typhoid, without primary lesions and without glandular enlargements"

The article describes seven cases seen in Central Kentucky, all of whom contracted the disease from handling killed rabbits. Large numbers of wild rabbits had died in recent years from an unrecognized plague. The author says

"Six of seven cases reported in this paper are of the ulceroglandular type, the other being the typhoid type. All seven cases received their infection from preparing rabbits for food. No cases of the glandular type without primary lesions have come under my observation."

"The average period of incubation definitely determined by Francis in 49 cases was slightly over three days. Incubation period in the seven cases reported herein was six, five, three, two and two days and two unknown. The onset is sudden, often occurring while the patient is at work, and is manifested characteristically by headache, vomiting, chilliness, chills, aching bodily pains, sweating, prostration and fever."

"Within 24 to 36 hours after the onset the site of infection becomes manifest as a painful swollen, inflamed papule which breaks down, liberating a necrotic core or plug and leaving an ulcer about three-eighths inch in diameter, with

raised edges and having a punched-out appearance, on healing the ulcer is replaced by scar tissue

"In about half of the cases the lymph glands suppurate, an abscess rupturing through a soft, thin spot in the skin. Suppuration of these enlarged glands has occurred as late as the tenth month. In the other half of the cases the glands do not break down, but remain hard, palpable and rather tender for two or three months, gradually returning to normal. In one of the reported cases a large tender gland was present in the axilla after two years.

"The oculoglandular cases follow the general description given above, but with primary inflammation or ulcer in the conjunctival sac instead of the skin.

"In the typhoidal type, fever was the only outstanding symptom. Prostration, recurring chills and sweats occur as in glandular enlargements. Following the initial fever, which lasts one, two or three days, is a secondary rise to the original height, after which there is a gradual decline to normal, the whole fibrile period lasting from two to three weeks.

"Convalescence is slow. It is rare for a patient to be at work again at the end of a month, usually the second month is spent lying about the house owing to weakness on exertion, and during the third month only half time work is performed. Some have not entirely returned to normal for six months or even a year. Recovery finally occurs without evident sequelae.

"The diagnosis is confirmed (1) By obtaining an agglutination of bacterium tularensis by blood serum collected in the second week of illness, (2) By isolation of bacterium tularensis from guinea pigs inoculated with material taken as early as the first week from the primary lesion or enlarged glands or blood of the patient.

"A negative Widal in a case simulating typhoid fever should immediately suggest the possibility of tularemia and the blood serum should be tested for agglutination and bacterium tularensis. According to E. Francis, 'The persistence of agglutinins in the blood of patients who have recovered, however, is a notable and fortunate occurrence, so that the serum from patients who have been well for several years is of great diagnostic value.'"

## For Ultra-Violet Radiation and Artificial Sunlight

The Ellis Carbon Arc is offered by one of the oldest and largest arc lamp manufacturers.

### Advantages

Uses long burning 12-inch carbons, all makes, which produce desired spectra—ultra violet to infra red. Automatic feed mechanism has successfully stood up under years of hard daily use—recently selected by the U S Navy on a large lamp order. Current 10-50 amperes—yielding adequate volume of radiation for all needs, average office to high intensity work. A. C. or D. C. operation. Refined appearance. Full set of local applicators. Ball bearing casters and counterbalance. Sold on trial on convenient terms at a reasonable price consistent with quality of materials and workmanship.

This New Book,

"The Carbon Arc"

—a conservatively written treatise containing 64 pages of scientific data. 23 spectrograms; 20 illustrations. 10 showing lamp in actual use; detailed technique and medical opinions, a valuable book you should have.

## THE RESULTS OBTAINED BY VARIOUS METHODS OF TREATMENT IN 622 CASES OF BLADDER TUMORS\*

By W W SCOTT, M D, and ROBERT W McKAY, M D, BALTIMORE, MD †

From the Brady Urological Institute Johns Hopkins Hospital Baltimore, Md.

IT is a well recognized fact that gross hematuria has its most frequent origin in bladder tumors. It is further well known that practically all of the more malignant types of tumor pass through a relative benign stage at which time their response to the more simple therapeutic measures is most satisfactory. Except for those cases in which the origin of hematuria is clinically evident it is necessary to regard the case tentatively, at least, as one of bladder tumor until this possibility has been eliminated by a cystoscopic examination. It is only by this means that we can hope to discover tumors in their early stages.

Four years ago one of us in collaboration with Dr. Hugh H. Young<sup>1</sup> reported the results obtained in the Brady Urological Institute by various methods of treatment in 380 cases of bladder tumor. Two years later we again brought our series up to date, and published our findings in *Young's Practice of Urology*<sup>2</sup>. Since then the addition of many new cases, as well as a careful check of the old ones has added much to our knowledge of the ultimate results.

**The Frequency of Occurrence**—In our series of 622 cases, the relative frequency with which the various types of bladder tumors occurred is stated in Table 1.

Of course, the adenocarcinoma and the squamous cell carcinomas are but special types of infiltrating carcinomas, but because they are not commonly found in the bladder, they have been classified separately. It is interesting to note that in 207 cases (33 per cent of the total number studied) papillomata were found. MacKenzie<sup>3</sup> in a study of 228 cases found that 48 per cent of them were benign. In a study of 222 cases Lower<sup>4</sup> reports that 51 per cent

were benign, Fuch<sup>5</sup> reporting 135 cases found non-carcinomatous growths in 42 per cent of the cases. Albarran, in a histological study of 98 tumors of the bladder, found that about 30 per cent of them were papillomata.

TABLE 1

Types of Bladder Tumor and Their Frequency of Occurrence	Number
TYPE OF TUMOR	
Benign papilloma	92
Malignant papilloma	105
Papilloma, not classified	8
Papillary carcinoma	141
Infiltrating carcinoma	271
Adenocarcinoma	1
Squamous cell carcinoma	2
Basal cell carcinoma	1
Dermoid cyst	1
Total	622

**Age of Onset**—The age of onset and the form of treatment are presented in Table 2.

The youngest patient appearing in the Brady Urological Clinic with a bladder tumor was a boy fifteen years of age who had a benign papilloma. One man 83 years of age appeared in the clinic with an infiltrating carcinoma of the bladder. Only ten patients in this series were less than 30 years of age. The majority of benign and malignant papillomas occurred between forty and fifty-nine years of age, whereas the greater number of carcinomas occurred between fifty and fifty-nine years of age.

**Sex**—In view of the fact that these statistics were obtained from a clinic in which most of the patients are male, no conclusions can be drawn regarding the relative frequency of occurrence in the male and female. Practically all the modern writers on this subject, however, agree that bladder tumors occur much more frequently in the male than in the female.

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N. Y., May 10, 1927.

† We wish to thank Drs. Young, Frontz and Colston for the privilege of using their cases in this analysis.

TABLE 2

*Age of Onset in 622 Cases of Bladder Tumor and the Treatment Used*

TREATMENT	No of cases	Age not given	10 years	19- 20 years	20- 29 years	30- 39 years	40-49 years	50-59 years	60-69 years	70-79 years	80-89 years

Total	622	39	1	9	51	103	172	166	76	5	

*Location of Tumors in Bladder*—In our series the location of the tumors in 615 cases is shown in the following table, No 3

TABLE 3

*Location of Tumors in Bladder 615 Cases*

SITE OF TUMOR	Number
Anterior bladder wall	76
Vertex of bladder	12
Posterior bladder wall	94
Vesical orifice	66
Middle of trigone	39
Region of left ureteral orifice	74
Region of right ureteral orifice	104
Left lateral wall	94
Right lateral wall	56
Total	615

There were 283 tumors located on the vesical orifice, trigone and about the ureteral orifices. In view of the fact that 43 per cent of the tumors in this study were infiltrating carcinomas, one can estimate that about 114 of the growths in the above mentioned localities were infiltrating in type, making resection very difficult and in many instances, impossible. The other tumors in these localities were, for the most part, of the types that respond to fulguration alone, or radium, or radiation plus fulguration. It will be seen that there were but 74 cases in which the growth occurred about the left ureteral orifice as compared with 104 cases having tumor similarly located on the right side. Many more tumors, however, were found on the bladder wall in the neighborhood of the left ureter than the right.

#### BRIEF DESCRIPTION OF THE VARIOUS TYPES OF TUMOR FOUND IN THIS SERIES

In this study we have followed quite closely the classification of epithelial bladder tumors advocated by the late Dr J T Geraghty. For the purposes of interpretation, a very brief description of each type commonly found, presenting

the salient gross and microscopic characteristics seems necessary.

1 *Papillomata*—Tumors of this group are divided into two types, benign and malignant papilloma.

A *Benign Papilloma*—This type occurs in two distinct varieties, the villous and pedunculated tumors. On cystoscopic examination the villous tumors appear as delicate, friable, wavy, pale filaments of various lengths that spring separately from the vesical mucosa and respond quickly to fulguration. The pedunculated variety, as indicated by its name, has a definite pedicle from which spring friable, relatively short and quite compact papillae. Its surface is not necrotic and the mucosa to which the pedicle is attached is freely movable and, therefore, not adherent to the underlying structures of the bladder. The microscopic picture of the benign varieties is quite characteristic. The connective tissue axis usually extends at right angles to the basement membrane of the bladder mucosa and the pedicle of the tumor. It has a definite basal layer of cells which are uniform in size and shape and orderly in arrangement. The next layer is composed of "long-tailed" cells and above these the epithelial cells tend to assume the characteristics of normal bladder mucosa. Their nuclei are like in size, stain alike, and mitotic figures are absent. The papillae are not fused.

B *Malignant Papilloma*—This type seems to be a sort of intermediary stage between the pedunculated benign papilloma and the papillary carcinoma, and it is frequently quite difficult on cystoscopic examination to differentiate it from either of these. On cystoscopic examination the pedicle, which is usually quite well formed, is seen to have springing from its surface short papillae that are compact and sometimes fused near the base. Due to a tendency towards implantation these tumors are more frequently found to be multiple than the pedunculated benign tumors. As a rule, this type is deeper pink in

color than the pedunculated benign variety, and has an irregular contour, resulting in a sort of a raspberry-like appearance. Unlike the papillary carcinoma no necrotic areas are found on its surface, and no signs of infiltration are seen about its base. Its pedicle is not attached to underlying structures of the bladder. When fulgurated the resulting slough quickly disappears, whereas in the papillary carcinoma, the slough is quite persistent. On microscopic examination it differs from the benign papilloma in that its epithelial cells do not have a uniform arrangement in layers and the "long-tailed" cells are decreased in number or absent. There is considerable variation of the cells in regard to size and staining characteristics of the nuclei and the nucleoli are usually more prominent than normal. The papillae are not infrequently fused.

It is perhaps well to emphasize at this time the fact that it is not uncommon to find in tumors which are for the most part typically malignant papillomas, areas that are microscopically benign. On the other hand, microscopic areas of carcinoma have been found in tumors, the remainder of which have been histologically benign. Therefore, it would seem that the form of therapy indicated should be determined, where possible, by the combined cystoscopic and microscopic findings.

**2 Papillary Carcinomas**—Villous or papillary tumors having infiltration of the connective tissue stalks of their papillae and their pedicles or which infiltrate the bladder wall are known as papillary carcinomas. The cystoscopic picture differs from that of the malignant papilloma in that the pedicle is usually shorter and broader, the papillae usually fused, and many times there are necrotic areas on its surface. In the presence of infection the tumors are quite often covered by a mucopurulent material. Infiltration of the bladder wall is indicated by nodular elevations of the mucosa and inflammatory reaction about the pedicle. The surface slough caused by fulguration is quite persistent. There is another type of papillary carcinoma, probably related to the villous type of benign epithelioma of the bladder which begins as a group of discrete short papillary growths that tend to fuse, forming a flat, sessile tumor of the bladder in which infiltration quickly occurs. The microscopic picture differs from that of the malignant papilloma in that the cells are more lawless in character and extent of growth, and there is invasion of the basement membrane of the papilla, the pedicle or the bladder wall.

**3 Infiltrating Carcinomas**—Most of the tumors appearing under this classification were really extensive infiltrating papillary carcinomas, whose pedunculated surfaces have sloughed away. On cystoscopic examination one finds a sloughing, necrotic, ulcerated surface having a greyish base

and a somewhat irregular elevated border. Many times small calcareous deposits are found attached to the ulcerated surface of the tumor. As a rule, the bladder is infiltrated over a much broader area than represented by the ulcerated surface, the infiltration being indicated by nodular elevations of the mucosa and inflammatory reaction. The histological picture is that of an extensive invasion of the bladder wall with lawless epithelial cells which here and there retain their papillary arrangement.

Another form of infiltrating carcinoma of the bladder found occasionally was the so-called scirrhous tumor. These tumors which are seldom multiple are found to have on cystoscopic examination a smooth, rounded, somewhat lobulated surface, across which zigzag fissures run. Their intravesical portion is not covered by vegetations or papillae and their base is usually broader than the surface. On microscopic examination numerous small nests of epithelial cells varying greatly in size, shape and staining characteristics and accompanied by a considerable amount of connective tissue are found extensively invading the bladder wall.

The third form of infiltrating carcinoma found on three occasions is almost entirely intramural in location. The surface does not protrude into the bladder cavity, but involves the whole wall, resulting in a greatly thickened bladder of cartilagenous consistence and markedly contracted. On cystoscopy the mucosal surface, because of the presence of numerous small irregular nodules and sometimes small ulcerative areas, presents a picture not unlike that of ulcerative cystitis. On microscopic examination extensive carcinomatous infiltration of the bladder wall is found.

Only two squamous cell carcinomas were found in our series. These appeared as extensive growths deeply infiltrating the bladder wall. On microscopic study pearly bodies and other characteristics of squamous carcinomas found elsewhere in the body were present.

The one adenocarcinoma found in this study in the gross appeared as an extensive flat ulcerative infiltrating tumor of the bladder wall. On microscopic examination typical gland formation in an extensive stroma of connective tissue was present.

The basal cell carcinoma appeared on cystoscopic examination as a superficial ulcer about the borders of which the vesical mucosa was quite inflamed and congested. On microscopic examination a typical basal cell tumor, the cells of which extended down to, but did not involve the muscularis, was found.

**4 Dermoid Cyst**—The dermoid cyst was quite typical of similar cysts found elsewhere in the body.

**Classification According to Treatment**—In a study of this character, it is necessary to consider the various types of bladder tumors in relation

to the form of therapy used. In this manner, we are able to determine the most satisfactory way of treating each particular type. In the table below, it will be seen that ten distinct

on cystoscopic examination, (2) those free from symptoms, and (3) those in whom the tumor recurred and were re-treated and later had negative cystoscopic findings or were symptomless

TABLE 4  
*Various Types of Bladder Tumors and Their Treatment 622 Cases*

methods were used. We have also included the pathological classification of 84 cases that received no treatment.

*Comment*—It is quite evident as one studies this table that in many instances the treatment was not appropriate. Many of the earlier cases were seen before the introduction of the more modern and satisfactory methods of treating bladder tumors. Other patients, because of old age, extreme prostration, extensive suprapubic scars from previous operations and secondary complications due to cardiac disease, renal insufficiency, etc., were not subjected to the more radical yet more appropriate forms of therapy. With the passing of years the introduction of better methods of treatment as well as more advanced ideas in regard to classification of bladder tumors with reference to the most appropriate form of therapy for each type of tumor has brought about much better results.

#### RESULTS OBTAINED BY VARIOUS METHODS OF TREATMENT

Insofar as possible, each patient has been followed from the time of his or her first appearance in the clinic. Owing to a custom of requesting the patients to return at stated intervals for cystoscopic examination, a large number of them have been observed very closely over a considerable period of time. Those unable to return because of financial or other reasons, have followed by means of questionnaires. The patients reported alive and well are divided into three groups, (1) those found free from tumor

#### I THE RESULTS OF FULGURATION ALONE IN TREATMENT OF BLADDER TUMORS, 59 CASES

The ages of the patients in this group were as follows: Ten to nineteen, 1, twenty to twenty-nine, 7, thirty to thirty-nine, 11, forty to forty-nine, 14, fifty to fifty-nine, 10, sixty to sixty-nine, 9, seventy to seventy-nine, 4, age not given, 3, total, 59. The youngest patient in our study was a boy 15 years of age who had a benign papilloma of the bladder.

Classification as to type of tumor made by the appearance of the growth on cystoscopic examination was confirmed in many instances by microscopic study of pieces removed before treatment was started. The types of tumor found were: benign papilloma, 45, malignant papilloma, 2, papillary carcinoma, 5, infiltrating carcinoma, 5, tumor designated only as papilloma, 2, total, 59. Results obtained in the treatment of these different types are shown in Table No. 5.

*Comment*—Of the 9 patients who died of tumor, 5 had infiltrating carcinomas, and 4 papillary carcinomas. In 5 of these the growths were so extensive that the patient's condition was hopeless from the start. We have found, however, that fulguration alone is of practically no value in treating papillary and infiltrating carcinomas except for hemostatic effect.

One patient having a papillary carcinoma was unimproved when he left the clinic.

One benign papilloma recurred, as such 11 years later, and was again destroyed by fulguration.

TABLE 5

Results of Fulguration Alone in Bladder Tumors 59 Cases

	Less than 1 yr	1 yr	2 yrs	3 yrs	4 yrs	5 yrs	6 yrs	7 yrs	8 yrs	9 yrs	10 yrs or more	Total
Alive and well—												
1 Cystoscopic examination		7	1	1	1	2	1		3		2	18
2. Symptomless			2	4		1		1	4		1	13
3 Recurred, re-treated, well											1	1
Recurred, unimproved			1									1
Recurred, dead	8											9
Dead, other causes	4			1			1		1	1	1	9
Not followed	8											8
Total	20	7	5	6	1	3	2	1	8	1	5	59

Since 45 of the 59 cases treated by fulguration were benign papillomas, we have analyzed them separately. The results are shown in the following table.

to fifty-nine, 44, sixty to sixty-nine, 43, seventy to seventy-nine, 20, age not given, 13, total, 163 cases. It is interesting to note that the onset occurred in more than half of the patients be-

Total	9	7	4	5	1	3	2	1	8	1	4	45

*Comment*—Of the 40 patients that were followed, not one died of tumor. Nine died of other causes, and 5 were not followed. These findings demonstrate quite conclusively that benign tumors can be destroyed by fulguration. In two instances the growth recurred, and was again destroyed by this method.

## II. RESULTS OBTAINED BY RADIUM WITH CYSTOSCOPIC APPLICATOR AND FULGURATION IN BLADDER TUMORS 163 CASES

Most of these patients received 100 milligram hours of radium with each treatment. Some of them, especially those in which the growth was extensive, and the type of tumor quite malignant, received 200 milligram hour exposures of radium. The malignant papillomas received on the average about 500 milligram hours of radium and then were destroyed by fulguration. In the very recent cases the malignant tumors were destroyed by fulguration and then radium was applied to the base of the tumor to prevent recurrence. The more malignant the tumor and the greater its size, the more radiation the patient received before fulguration was attempted.

The ages of the patients in this group were as follows: Twenty to twenty-nine, 2, thirty to thirty-nine, 13, forty to forty-nine, 28, fifty

tween fifty and sixty-nine years of age. The more advanced age of onset in this group, as compared to the previous one, can be explained by the increase in malignant types.

The types of tumors in this group determined by cystoscopic or microscopic examination were as follows: Benign papilloma, 37, malignant papilloma, 64, papillary carcinoma, 38, infiltrating carcinoma, 24, total number of cases, 163. Under the type of infiltrating carcinoma there were one adenocarcinoma and one squamous cell carcinoma.

The results obtained by treatment are designated in Table No. 7.

*Summary*—Of the 32 patients in this group that died of tumor, 10 had papillary carcinoma, 17 infiltrating carcinoma, 4 malignant papilloma, and 1 adenocarcinoma. Over 46 per cent of the patients were well one year or more. Eleven per cent of the patients died from some cause other than tumor, and consequently these should be added to the 46 per cent that were well one year or more. Not one of the 37 patients having benign papillomas died of tumor. Ten of the 39 patients having papillary carcinoma died of tumor, while 3 were unimproved and 7 were not followed. Only one infiltrating carcinoma was well one year or more.

There were so many malignant papillomas in this group that it seemed advisable to include a separate table giving the results obtained by treatment of this particular type (See Table 8)

scopic or microscopic examination was as follows: Benign papilloma, 3, malignant papilloma, 8, papillary carcinoma, 22, infiltrating carcinoma, 26, total number of cases, 59

TABLE 8.

*Results of Radium Cystoscopically plus Fulguration in Malignant Papilloma 62 Cases*

	1 yr	2 yrs	3 yrs	4 yrs	5 yrs	6 yrs	7 yrs	8 yrs	9 yrs	10 yrs or more	Total

Recurred, dead	1	2						1			4
Dead, other causes	3			2		1			1	1	8
Not followed	9										9
Total	23	9	9	7	2	4	1	1	3	5	62

**Summary**—In 2 of the 4 cases reported dead from malignant papilloma the growths were destroyed but recurred a second time as a definite infiltrating carcinoma resulting in metastasis and death. Six patients were unimproved by treatment and 9 were not followed. The remainder were well one year or more or died from other causes. It is, therefore, quite evident that the malignant papilloma usually respond very well to radium plus fulguration.

### III CASES TREATED WITH CYSTOSCOPIC RADIUM APPLICATOR ALONE OR PLUS OTHER METHODS OF APPLICATION 59 CASES

In most of these cases the radium could be placed directly upon the bladder tumor by means of Young's cystoscopic applicator. In a number of instances the growth had extended into the posterior urethra making necessary urethral applications. In other cases, especially where induration of the bladder wall could be felt on rectal or vaginal examination, the radium applied by cystoscopic applicator was reinforced by rectal or vaginal applications.

The ages of the patients were as follows: Thirty to thirty-nine, 3, forty to forty-nine, 9, fifty to fifty-nine, 19, sixty to sixty-nine, 14, seventy to seventy-nine, 10, age not given, 4, total, 59 cases.

The type of tumor as determined by cyste-

The results obtained by this treatment are shown in Table No 9

TABLE 9

*Results Obtained by Cystoscopic Application of Radium Alone or Plus Other Methods of Application 59 Cases*

	Less than 1 yr	1 yr	2 yrs	3 yrs	4 yrs	5 yrs	Total

2 Symptomless			1		2	3	6
Recurred, unimproved		2					2
Recurred, dead	12	12	2		2	1	29
Dead, other causes	1	2	2				5
Total							59

**Summary**—Of the 59 cases in this group 11 were well, six of them 3 years or more, two 2 years and three less than 1 year after beginning treatment. In addition there were two patients with benign papilloma that were not classified as well, although no tumor was present when discharged. One of these was killed in an accident one year later, and the other was not followed. These have been classified under deaths due to other causes. Two cases of infiltrating carcinoma were well 5 years or more, and one less than a year. Two patients having papillary carcinoma were well 4 years or more and two were found to be free from tumor on cystoscopic examination less than a year after their first treatment. Three cases of malignant papil-

loma were well 3 years or more. The high mortality in this group was due to the fact that almost half of the tumors were infiltrating carcinomas. The fact that three infiltrating carcinomas, however, were apparently destroyed by this method, indicates that occasionally this type yields to radium alone.

#### IV CASES TREATED WITH RADIUM BY MEANS OTHER THAN CYSTOSCOPIC APPLICATION 12 CASES

In all of these cases the growth was so extensive as to make them practically hopeless from the start.

The ages of the patients were as follows: Thirty to thirty-nine, 1, forty to forty-nine, 3, fifty to fifty-nine, 3, sixty to sixty-nine, 1, seventy to seventy-nine, 1, age not given, 3, total number of cases, 12.

Ten of the 12 tumors were infiltrating carcinomas, one was an extensive papillary carcinoma and one a very extensive malignant papilloma.

The radium was applied as follows: Massive doses to the abdominal wall, 3, through a fresh suprapubic wound or a fistula, 7, through the rectum, 1, and through a suprapubic fistula and to rectum, 1.

The results obtained were most unsatisfactory. Nine of the patients died in less than a year, and the others within a year from the time treatment was started.

#### V RESULTS OBTAINED BY SUPRAPUBIC IMPLANTATION OF RADIUM INTO VESICAL TUMOR. 35 CASES

The ages of the patients were as follows: Thirty to thirty-nine, 3, forty to forty-nine, 2, fifty to fifty-nine, 16, sixty to sixty-nine, 7, seventy to seventy-nine, 5, age not given, 2, total, 35.

The following types of tumors were found: Malignant papilloma, 1, papillary carcinoma, 14, infiltrating carcinoma, 19, and squamous cell carcinoma, 1.

*Methods of Implantation*—The bladder was exposed, partially mobilized and then opened very wide, great care being exercised to avoid the tumor. The danger from implantation of tumor tissue was minimized as much as possible by covering the normal bladder mucosa about the base of the tumor with moist bichloride of mercury packs. In 21 cases the tumor was destroyed to the bladder level by cauterization and then implanted with radium. In 14 cases the tumor was implanted with radium without preliminary cauterization. In the first few cases emanation seeds of 2 or 3 millicuries were implanted and allowed to remain in situ. The dosage from these proved to be too great and later emanations of 1 millicurie were used. During the last five years, however, small platinum needles containing 1 milligram of the radium element have been im-

planted into the tumor and removed after 48 hours or more. Where the growth was extensive, and the infiltration quite deep, the radiation obtained by the needles was reinforced by the use of radium spears containing 10 to 12½ milligrams of the element. We have at the Clinic 20 platinum needle points each containing one milligram of radium, three spears of 10 milligrams each, and two of 12½ milligrams each. In most cases all of these were used. The details of use are given in Young's Practice of Urology. We also use two tubes containing 100 milligrams of radium element in the urethra, when the carcinoma invades the vesical neck. The patient received on an average about 2,400 milligram hours of radium. In this manner the tumor and the bladder tissue approximating it received a large amount of radiation. The results obtained by this method are summarized in Table 10.

TABLE 10

*Suprapubic Implantation of Radium into Vesical Tumor  
35 Cases*

Recurred, unimproved			2				2
Recurred, dead	11	11	1				23
Dead, other causes	3						3
Not followed	1						1
Total							35

*Summary*—In this group six patients are well 1 year or more. One patient, who had an infiltrating carcinoma, is well more than 5 years and two others are symptomless more than 5 years. Three patients who had papillary carcinoma were found to be free from tumor on cystoscopic examination 1, 2 and 3 years after operation. One patient whose tumor was cauterized before it was implanted, died of streptococcus hemolyticus septicemia a short time after his operation.

Considering that all the tumors in this group were extensive and situated in positions which made resection impossible, the results obtained warrant further attempts with this form of therapy.

#### VI CASES TREATED BY SUPRAPUBIC RESECTION OF BLADDER TUMOR 72 CASES

The ages of the patients in this group were as follows: Thirty to thirty-nine, 2, forty to forty-nine, 8, fifty to fifty-nine, 23, sixty to sixty-nine, 29, seventy to seventy-nine, 6, age not given, 4, total, 72.

The type of tumor in these cases was as follows: Malignant papilloma, 3, papillary carcinoma, 23, infiltrating carcinoma, 44, dermoid cyst, 1, basal cell carcinoma, 1, total 72.

In the table No 11 the results of treatment are shown.

TABLE 11

*Results Obtained by Suprapubic Resection of Bladder Tumor 72 Cases*

Dead, other causes				1	2		1					4
Not followed	5	1										6
Total	20	21	4	4	4	5	5	2	1	2	4	72

*Summary*—In all cases except those in which the growth was small and located on the anterior wall, the bladder was mobilized as much as possible before resection of the tumor was started. In a number of cases transperitoneal resection was necessary.

The tumors were located as follows: Anterior wall, 15, lateral walls, 19, posterior wall, 16, trigone and ureteral orifices, 15, and vesical orifice, 7.

When one considers that 62 per cent of the cases treated in this group were infiltrating carcinomas, and 32 per cent were papillary carcinomas, the results obtained by this form of therapy were surprisingly good. There are 26 patients well one year or more, 16 of them 5 years or more. Also 4 other patients died from other causes three years or more after operation, and insofar as we were able to determine, had no bladder symptoms at time of death. Of 26 patients well one year or more, 13 had infiltrating carcinomas, 9 papillary carcinomas, 3 malignant papillomas and 1 a dermoid cyst. In two instances the growth recurred, but responded to radium plus fulguration.

The ureter was transplanted 15 times. Four of these patients are alive 9 years or more and 2 died from other causes several years after the operation.

There were 6 post-operative deaths. Of these 2 were due to pulmonary emboli and 1 to thrombophlebitis. Such findings as these emphasize the importance of exercising the utmost care in all operative manipulations.

This clearly demonstrates that resection, where possible, is the most satisfactory method of treating infiltrating carcinomas of the bladder.

#### VII CASES TREATED BY SUPRAPUBIC CAUTERIZATION OF TUMOR 37 CASES

In this group the growth was exposed and the surrounding mucosa protected in the same manner described for resection of bladder tumor. If the pedicle was long the outer surface of the tumor was seared with the cautery blade, and then the pedicle was cut across. The remaining stump of the pedicle and the infiltrated portion of the bladder were deeply cauterized. In the flat type of growth the surface as well as the infiltrated portion of the bladder was immediately destroyed by deep cauterization. In a number of instances the vesical orifice was involved and in these cases extensive cauterization of this region was carried out. Suprapubic drainage was used in each case.

The ages of these cases were as follows: Thirty to thirty-nine, 15, forty to forty-nine, 4, fifty to fifty-nine, 8, sixty to sixty-nine, 18, seventy to seventy-nine, 3.

The types of tumor diagnosed by cystoscopic and microscopic examinations and verified at operation were as follows: Papilloma, not classified, 1, benign papilloma, 3, malignant papilloma, 7, papillary carcinoma, 11, and infiltrating carcinoma, 15.

The results obtained are shown in Table No 12.

TABLE 12

*Results of Cauterization Alone in Bladder Tumors 37 Cases*

Recurred, dead	5	12	3							1		21
Dead, other causes	2											2
Not followed	1											1
Total	8	14	5	1	1	0	2	0	2	1	3	37

*Summary*—There are 12 patients in this group well one year or more after operation. Only two of these had infiltrating carcinomas. Two patients who had papillary carcinomas are well 4 years or more. The rest of the patients that are well one year or more had either benign or malignant papillomas, types that respond very well to radium plus fulguration. These, in the light of our present knowledge regarding the treatment of bladder tumors, received much more radical therapy than necessary. Two patients died from thrombophlebitis and one of septicemia shortly after operation. In all three of these cases radium was not used and it was necessary to cauterize very deeply, a procedure which evidently adds greatly to the postoperative risks. These findings seem to indicate that better results can be obtained by cauterizing the tumor down to the level of the bladder mucosa and then implanting the deeper portions of the growth with radium, than with deep cauterization alone.

#### VIII RESULTS OBTAINED BY SUPRAPUBIC TREATMENT WITH DIATHERMY 4 CASES

Insofar as the exposure of the tumor and the protection of the normal bladder mucosa were concerned, the method employed here was the same as in cauterization of bladder tumors. In one instance the pedicle was cut across with the endotherm knife and the infiltrated portion of the bladder treated by deep diathermy. In the remaining three cases flat infiltrating carcinomas were found and apparently destroyed by deep diathermy.

The patients were 47, 57, 58 and 71 years of age.

All four of the tumors were infiltrating carcinomas.

It is only fair to state that no worthwhile conclusions can be drawn from a series of four cases. One patient was free from tumor a year after his operation, two others died of tumor within a year, and there was one postoperative death. These findings are not in keeping with those of Dr. Corbus,<sup>6</sup> who reports only four deaths from tumor in a series of 31 cases treated by this method. Unfortunately, the tumors in that series were not classified as to type and, therefore, one is unable to draw any conclusions as to the effect of diathermy on infiltrating carcinomas of the bladder.

#### IX RESULTS OBTAINED BY OTHER OPERATIVE MEASURES 43 CASES

The ages of these 43 patients were as follows: Thirty to thirty-nine, 2; forty to forty-nine, 9; fifty to fifty-nine, 10; sixty to sixty-nine, 13; seventy to seventy-nine, 4; eighty to eighty-nine, 2; ages not given, 3.

The following types of tumor were found: Benign papilloma, 2; malignant papilloma, 4;

papillary carcinoma, 4; infiltrating carcinoma, 32; and papilloma not classified, 1.

The methods of procedure employed are given in Table No. 13.

TABLE 13

*Various Other Operative Measures Employed in the Treatment of Bladder Tumors 43 Cases*

Suprapubic drainage	22
Excision of tumor	4
Curettage of tumor	3
Suprapubic fulguration of tumor	2
Incomplete resection	2
Tumor twisted off with clamps	2
Removal by torsion and forceps	1
Excision and curettage of base	1
Excision of tumor in a diverticulum	1
Punch operation for obstruction	1
Perineal prostatectomy and curettage of tumor	1
Suprapubic exploratory	1
Ureterostomy for obstruction	1
Suprapubic operation for extravasated urine	1
Total	43

*Summary*—Three patients in this group were cured of tumor. One of these had a benign papilloma which was twisted from the bladder wall and did not recur. A malignant papilloma which was excised recurred but was destroyed by fulguration. In the third case, a papilloma was fulgurated and then excised. This patient was well seven years after the operation. All three of these patients could have been cured by radium plus fulguration.

The presence of such a variety of operations can be explained by the fact that many of the patients visited the clinic before the more satisfactory methods of treating bladder tumors had been developed. For this reason and also because almost 80 per cent of the patients had extensive infiltrating carcinomas, the results obtained were very unsatisfactory.

#### X CASES TREATED BY X-RAY ALONE AND COMBINED WITH SOME OTHER FORM OF THERAPY 54 CASES

The ages of the patients in this group were as follows: thirty to thirty-nine, 1; forty to forty-nine, 11; fifty to fifty-nine, 16; sixty to sixty-nine, 15; seventy to seventy-nine, 7; eighty to eighty-nine, 1; ages not given, 3.

The following types of tumor were found: Benign papilloma, 1; malignant papilloma, 6; papillary carcinoma, 14; infiltrating carcinoma, 33.

Deep X-ray was combined with radium or radium plus fulguration in all but 10 cases in this group. In these cases the growth was so extensive as to prevent the satisfactory application of radium or the introduction of the radium instrument so painful as to make its use impossible. The results obtained are shown in Table No. 14.

TABLE 14

*Results of X-ray Alone and Combined with Some Other Form of Therapy 54 Cases*

	Less than 1 yr	1 yr	2 yrs	3 yrs	4 yrs	5 yrs	6 yrs	7 yrs	8 yrs	9 yrs	10 yrs. or more	Total

Dead, other causes												
Not followed	3											3
Total	18	21	8	3	2	0	0	0	0	2	0	54

**Summary**—Thirteen patients are well one year or more after their first treatment. Of these 1 patient had a benign papilloma, 4 malignant papilloma, 5 papillary carcinoma, and 3 infiltrating carcinoma. Inasmuch as all of these patients received radium applications before the deep X-ray therapy, it is difficult to estimate accurately the part played by the latter in the destruction of the growths. Our other studies have shown that benign and malignant papillomas respond to radium alone. There were also many papillary carcinomas and a few infiltrating carcinomas cured by the same therapy, so a better estimate of the curative value of deep X-ray can be obtained by a study of cases receiving only that particular therapy. There were 10 such cases and all of them died of tumor. However, most of them were so advanced as to be hopeless from the start.

Because some patients react violently to deep X-ray, it is necessary to follow each case very closely. There were 3 cases in which exitus was apparently hastened by this therapy.

In the cases that had received preliminary treatment with radium, the deep X-ray therapy seemed to be most effective. Although deep X-ray frequently stopped bleeding, radium applied cystoscopically gave better results in this respect. Deep X-ray diminished greatly pains due to nerve involvement.

Although deep X-ray therapy is another adjunct in the armamentarium of the urologist, it is of little value when used alone in the treatment of the more advanced infiltrating growths.

#### XI CASES NOT TREATED 84 CASES

For the sake of completeness and also to illustrate the unfortunate termination of those cases receiving no treatment, this group is included.

The ages were as follows: Thirty to thirty-nine, 10; forty to forty-nine, 14; fifty to fifty-nine, 21; sixty to sixty-nine, 17; seventy to seventy-nine, 16; eighty to eighty-nine, 2; ages not given 4.

The type of tumor present was as follows: Benign papilloma, 1; malignant papilloma, 9; papillary carcinoma 9; infiltrating carcinoma, 61; papilloma, not classified, 4.

It was impossible to follow 23 of these patients, but of the others, 36 died within one year and 25 within two years.

Although 61 of the patients had infiltrating carcinomas, a number of the patients could possibly have been cured had they not refused treatment.

#### CONCLUSIONS

The age of onset in this series of 622 cases of bladder tumors varied between 15 and 83 years of age.

Benign and malignant papillomas, for the most part, occurred in patients between 40 and 59 years of age, while the majority of the carcinomas appeared between the ages of 50 and 69.

The types of bladder tumors found in this series were classified as follows: Benign papilloma, 15 per cent; malignant papilloma, 17 per cent; papillary carcinoma, 22 per cent; infiltrating carcinoma, 44 per cent; papilloma not classified, 8 cases; squamous cell carcinoma, 2 cases; adeno-carcinoma basal cell carcinoma and dermoid cyst, 1 case each.

The essential factor in the treatment of bladder tumors is their proper classification as to the type of growth. This can best be accomplished by means of a thorough knowledge of the cystoscopic picture of each type of tumor supplemented by histological findings, presence of induration on rectal examination and the presence or absence of metastasis.

The tumor having been properly classified, it is not, as a rule, difficult to select the most appropriate form of therapy.

Benign papillomas always respond to fulguration alone, but these tumors often disappear much more rapidly when cystoscopic applications of radium are used in addition to fulguration. These tumors recur, and often it is necessary to have the patients return from time to time for cystoscopic examination over a period of several years after the primary growth has been destroyed.

Malignant papillomas very frequently respond to fulguration alone, but much more satisfactory results are obtained if the tumor is first thoroughly treated by cystoscopic applications of radium and then fulgurated. These tumors re-

cur more frequently than the benign type and this necessitates the patient's return for cystoscopic examination at intervals of every few months

Papillary carcinomas, if not too extensive, usually respond to radiation plus fulguration, and should first be subjected to this combined therapy. In a few cases where this therapy has failed the tumor has responded to X-ray. Should the methods mentioned above fail, the tumor should be resected if it is a favorable location for such a procedure. If its location is unfavorable, it should be cauterized superficially and implanted with radium or treated with deep diathermy.

All infiltrating carcinomas, if their location is favorable and the patient's general condition permits, should be resected. Where this is impossible the combined radium and deep X-ray therapy should be tried and if this fails, the tumor should be treated by cauterization and implantation of radium, if it is not too extensive.

The value of diathermy as a therapeutic measure in the treatment of infiltrating carcinomas of the bladder has not yet as yet been definitely established.

In our series deep X-ray, when used alone, has been disappointing from the standpoint of tumor destruction. However, it has been of great value in diminishing the intensity of pain due to nerve involvement.

This study confirms previous reports from this clinic showing that excellent results may be obtained by cystoscopic applications of radium and fulguration in definitely malignant tumors of the bladder when not too far advanced.

## LIVER FEEDING AS A THERAPEUTIC AGENT IN SUPPURATIVE CONDITIONS A PRELIMINARY REPORT

By HOMER L. NELMS, M.D., ALBANY, N. Y.

FOLLOWING the experimental work of Robschelt, Robbins and Whipple on the favorable influence of a liver diet on blood regeneration and the clinical application of this dietary principal in the management of pernicious anemia by Minot and Murphy, a new and effective therapeutic agent was at once placed at our disposal. The literature thus far is scant on the effectiveness of these measures but there can be no doubt that its use has a striking stimulating effect on the blood forming organs. Previous observations have dealt mostly with the influence of liver in pernicious anemia, a comparatively rare condition compared to the great mass of secondary anemias that physicians and surgeons see. With this thought in mind we have observed the influence of liver feedings in severe secondary anemias especially those following long drawn out suppurative conditions. The end results are as striking in this group of cases as in primary anemia and its general application opens up a much wider field of usefulness.

It is a well known fact that suppurative conditions anywhere have a tendency to deplete the blood, there is a decrease in the amount of hemoglobin and the number of red blood cells, although not in the same proportion as in primary anemia, however, the effects on the individual are the same, a prolonged convalescence and the ever-present susceptibility to intercurrent infections.

We believe that the use of liver shortens the period of convalescence, increases the patient's resistance and has a favorable influence on the course of the disease.

Our first observation was made on a patient with a suppurative arthritis who later developed a septicemia, the blood cultures being positive. The primary focus was drained and the general condition treated by supportive measures. At the end of ten weeks the temperature had returned to normal, there was no drainage, but the patient was extremely emaciated and suffering from a severe secondary anemia. The red blood count was 3,630,000, hemoglobin 58% and white blood count 15,000. The appetite was poor but the patient was allowed what she could take from a 3500 calorie diet and given injection of sodium cacodylate gr. 1, every other day. This was kept up for a period of about two weeks, with very little improvement in the general condition. By this time the blood count had dropped to R. B. C. 3,400,000 and the hemoglobin 50%. The W. B. C. remained 15,400. The temperature was still normal and a second blood culture was taken but no growth obtained after five days' incubation. It was at this stage that we decided to try the effects of liver feedings with iron in the form of Bland's pills, a procedure that had been recommended in pernicious anemia. There was a striking improvement in the patient's physical condition and a corresponding change

**Summary**—Thirteen patients are well one year or more after their first treatment. Of these 1 patient had a benign papilloma, 4 malignant papilloma, 5 papillary carcinoma, and 3 infiltrating carcinoma. Inasmuch as all of these patients received radium applications before the deep X-ray therapy, it is difficult to estimate accurately the part played by the latter in the destruction of the growths. Our other studies have shown that benign and malignant papillomas respond to radium alone. There were also many papillary carcinomas and a few infiltrating carcinomas cured by the same therapy, so a better estimate of the curative value of deep X-ray can be obtained by a study of cases receiving only that particular therapy. There were 10 such cases and all of them died of tumor. However, most of them were so advanced as to be hopeless from the start.

Because some patients react violently to deep X-ray, it is necessary to follow each case very closely. There were 3 cases in which exitus was apparently hastened by this therapy.

In the cases that had received preliminary treatment with radium, the deep X-ray therapy seemed to be most effective. Although deep X-ray frequently stopped bleeding, radium applied cystoscopically gave better results in this respect. Deep X-ray diminished greatly pains due to nerve involvement.

Although deep X-ray therapy is another adjunct in the armamentarium of the urologist, it is of little value when used alone in the treatment of the more advanced infiltrating growths.

#### XI CASES NOT TREATED 84 CASES

For the sake of completeness and also to illustrate the unfortunate termination of those cases receiving no treatment, this group is included.

The ages were as follows: Thirty to thirty-nine, 10; forty to forty-nine, 14; fifty to fifty-nine, 21; sixty to sixty-nine, 17; seventy to seventy-nine, 16; eighty to eighty-nine, 2; ages not given, 4.

The type of tumor present was as follows: Benign papilloma, 1; malignant papilloma, 9; papillary carcinoma, 9; infiltrating carcinoma, 61; papilloma, not classified, 4.

It was impossible to follow 23 of these patients, but of the others, 36 died within one year and 25 within two years.

Although 61 of the patients had infiltrating carcinomas, a number of the patients could possibly have been cured had they not refused treatment.

#### CONCLUSIONS

The age of onset in this series of 622 cases of bladder tumors varied between 15 and 83 years of age.

Benign and malignant papillomas, for the most part, occurred in patients between 40 and 59 years of age, while the majority of the carcinomas appeared between the ages of 50 and 69.

The types of bladder tumors found in this series were classified as follows: Benign papilloma, 15 per cent; malignant papilloma, 17 per cent; papillary carcinoma, 22 per cent; infiltrating carcinoma, 44 per cent; papilloma not classified, 8 cases; squamous cell carcinoma, 2 cases; adeno-carcinoma basal cell carcinoma and dermoid cyst, 1 case each.

The essential factor in the treatment of bladder tumors is their proper classification as to the type of growth. This can best be accomplished by means of a thorough knowledge of the cystoscopic picture of each type of tumor supplemented by histological findings, presence of induration on rectal examination and the presence or absence of metastasis.

The tumor having been properly classified, it is not, as a rule, difficult to select the most appropriate form of therapy.

Benign papillomas always respond to fulguration alone, but these tumors often disappear much more rapidly when cystoscopic applications of radium are used in addition to fulguration. These tumors recur, and often it is necessary to have the patients return from time to time for cystoscopic examination over a period of several years after the primary growth has been destroyed.

Malignant papillomas very frequently respond to fulguration alone, but much more satisfactory results are obtained if the tumor is first thoroughly treated by cystoscopic applications of radium and then fulgurated. These tumors re-

# PHOTOGRAPHS OF THE FUNDUS OCULI, NORMAL AND PATHOLOGICAL CONDITIONS, WITH CASE HISTORIES, SINGLE AND STEREOSCOPIC VIEWS

By ARTHUR J BEDELL, MD, ALBANY, N Y

The Lucien Howe Prize Essay of the Medical Society of the State of New York, 1927

**A**DVANCES in the art of medicine are always followed by scientific progress, so that now as a result of the epoch-making achievements of our professional predecessors, we can not only see the interior of the eye but also photograph it.

Ever since the introduction of the ophthalmoscope, ophthalmologists and clinicians have wished for a method of recording the appearance of the fundus. As a result, many cameras have been devised, notably those by Wolfe and Thorner. Both of these were laboratory instruments and were never used to any extent.

## THE CAMERA OF DIMMER

In 1911 Dimmer described his instrument and reported in several communications his findings, but unfortunately, his instrument was large, cumbersome and in no way adapted to routine clinical procedures. The illustration (Fig 1) shows the apparatus in use. One look is enough to convince a doubter that the average patient could never be placed before it. Dimmer's original work did much to increase interest in and add to the possibilities of photographing the eye grounds, but did little to advance the clinical side of photography.

## SALOMONSON'S RECORDING OPHTHALMOSCOPE

Salomonson, of Amsterdam, devised what was called a recording ophthalmoscope. His original instruments were modified and improved until at the meeting of the American Medical Association at Atlantic City in May, 1925, the camera illustrated was shown (Fig 2). By means of this instrument, it was possible to make a photograph, about 44 mm in diameter. The instrument consisted of two optical systems, one for

Fig 1—The Camera of Dimmer

Fig 2—Salomonson's Recording Ophthalmoscope

illuminating and the other for viewing and photographing the fundus. A beam of light from a small 6 ampere arc lamp passed through a condenser and a lens and formed an image of the condenser in the plane of an aplanatic aspherical lens. This illuminating beam was in turn reflected into the eye. When the instrument was in use, the fundus was focused under subdued light and the actual photograph was taken by the simultaneous exposure of the eye and the plate to the intense light for from 0.05 to 0.2 seconds. In practice, it was found that an exposure of 0.1 second generally sufficed. The design of the optical system eliminated all secondary reflections from the cornea and from the ophthalmoscope lens. The apparatus was mounted on a heavy stand and provided with three adjustments, so that it could be carefully adjusted close to the eye under observation. The pictures we have seen that were made with the instrument leave much to be desired.

In 1922, at an International Congress of Ophthalmology held in Washington, Nordenson of Upsala presented some pictures of the fundus made with his camera. After many modifications, the instrument was placed on the market in 1926.

in the blood picture as noted in the accompanying table.

Date	R B C	Hg %	W B C
Feb 17	3,400,000	50	15,430
Feb 23	3,600,000	55	11,400
Mar 3	4,000,000	60	10,000
Mar 17	4,600,000	70	9,860
Apr 1	5,650,000	80	9,320

We can not prove that these changes would not have taken place anyway, but on the other hand, here was a patient that had had the usual supportive measures for her condition with the possible exception of blood transfusions and in spite of them all did not gain very rapidly. The fact that there was a definite improvement in the clinical condition accompanied by a corresponding change in the blood picture and that these improvements dated from and accompanied the addition of liver and iron to the diet, we feel are matters that must seriously be considered as playing some part in the outcome of this case.

Our second observation was made on a patient that developed a wound infection following an interval appendix. This was later complicated by a septic sore throat, acute otitis media, mastoiditis and erysipelas. One month after operation the R B C was 4,000,000 and the Hg 45%. W B C 11,400. Liver and Bland's pills were then ordered and within two weeks the Hg had jumped to 60% and the R B C to 4,600,000. Two weeks later the R B C was 5,000,000 and the Hg 80%, and the patient is now no worse from her various experiences.

Encouraged by these and a few less striking cases, the thought has occurred that if secondary anemia can be cured by the use of liver and iron, can it not be prevented, or at least in some degree controlled by the same agents? Working on this theory we are now adding liver in liquid form and Bland's pills to the otherwise general diet in all suppurative conditions. This is done immediately after the surgical indications have been

met and the patient can tolerate a general diet. That there is some justification for this procedure is illustrated by the following case.

Mr H R age 29, was admitted to the hospital with an intense cellulitis of his arm extending from the wrist to the shoulder. Duration of symptoms four days. His temperature was 104, pulse 120 and for the past twelve hours he had been having chills. On examination there was a definite area of softening near the elbow so that thorough drainage was indicated. He was given a general anesthetic and six through and through drainage tubes placed in the arm. His temperature subsided and one week after operation the R B C was 4,400,000, Hg 70%, W.B.C. 14,500. This man was given liver and iron at once and two weeks later the R B C was 4,800,000, Hg 87%, and W B C 9,250. He left the hospital at the end of three weeks. There was no drainage from the arm except, of course, from the granulating areas at the site of the drainage tubes. It was agreed by all who saw this man that his convalescence was an especially striking one.

One swallow does not make a summer, a few encouraging reports from one lone source do not establish a surgical principle and we admit that our observations are too recent to draw any definite conclusions. This report therefore, is in no measure conclusive, we make it in the hope that it will stimulate others in this line of endeavor and that the possibilities of this dietary adjunct may not be long overestimated.

Fig 5—Phantom View of the Nordenson Camera.

the time diaphragm swings the shutter filter out of place and allows the intense light to flood the interior of the eye and by pushing the reflecting shutter up, exposes the plate. Immediately after the exposure, the patient complains of a dark spot, which disappears in a moment if the eye is kept closed.

If a good picture is to be secured, it is absolutely necessary that the patient's eye remain stationary, that the photographic plate be rapid and that the fundus be accurately focused. This means the careful co-operation of patient, assistant and operator. If the patient blinks, there is a light reflex which blurs the picture, if he moves, the object is out of focus, and if the plate is too slow, the film is so thin that it is impossible to bring out the finer details of the interior of the eye.

#### STEREOSCOPIC PHOTOGRAPHY

For stereoscopic photography, two plates are made at different angles. This, of course, means two separate exposures, but if the patient's fixation is constant, we have found that by displacing the camera laterally 24 mm it is possible to get an excellent perspective. Even in cases where the horizontal level has not been main-

tained, a slight tilting of the photographs will bring out the stereoscopic detail.

So few articles have appeared in recent literature regarding the increasing desirability of eyeground photographs, that the subject warrants detailed consideration. We believe that the presentation of original pictures will assist in proving the importance of photographic records.

#### CLINICAL REPORTS

Our study consisted in the making, correlating, and clinical classification of more than 600 eyes. The patients were of both sexes and varied in age from 6 to 81 years. Eyes with clear media were photographed, and many others with corneal, lenticular and vitreous opacities. Pictures were made of normal fundi, of high hyperopes, of high and low myopes, and of aphakics, also of those in which the normal nerve was clearly outlined, and others in which the variations from health were minor, and still others in which the changes were gross. The various pathological processes in the retina, choroid, and optic nerve have been photographed and excellent pictures of the usual and unusual fundus changes have been secured. From the extensive and ever increasing material, several

Fig 3—The Nordenson Camera, right side.

#### THE NORDENSON CAMERA

The Nordenson camera is based on the Gullstrand principle used in central ophthalmoscopy. The instrument is placed on the ordinary ophthalmological stand with the usual compound slide. The illustrations 3, 4 and 5 show the details of the instrument. The source of illumination is a 5 ampere arc lamp, which must be on direct current if the best results are to be obtained. The working drawing shows the course of the light ray passing from X through the condensing lens, reflected by the prism through a filter of iron oxyfial glass through another filter on the shutter, through a reflecting prism to and finally through the condensing lens into the patient's eye. The course of the depicting rays is shown by a line extending from the patient's eye. The rays are reflected by a silvered mirror through two condensing lenses into the observing ocular.

The carbon arc must be so placed as to insure the most intense brilliance. Occasionally, the arc may be maintained by the automatic clock-work on the side of the instrument, but in practice we find that it is better to adjust the carbons by the hand screw.

The fundus must be accurately focused on the plate, which is done by moving the slide screw recognized as being in front of the camera box. The time of exposure is controlled by a mechanical spring action. The actual time is automatically arranged by the position of an arrow

on the dial. This dial has numbers ranging from "0" to "6," which correspond to 1-8 to 1-22 of a second. The large projecting column on the plate consists of two knurled nuts. The upper one regulates the spring action and the lower one is set for the exposure by placing the arrow on its side at the given mark.

#### METHOD OF EXAMINATION

The camera can only be used in a black room. The patient's pupil must be widely dilated, the patient comfortably placed in front of the instrument with the chin and forehead under control. The photographic plate is placed in the opening of the camera box, the light is focused as a narrow crescent on the lower pupillary margin of the iris and the patient directed to look in the proper direction, so that the portion of the fundus desired may be directly illuminated. Fixation is maintained by watching a small cross of light, which is adjusted to the patient's eye.

The fundus is accurately focused through the eye piece, so that the picture is taken under the direct observation of the examiner, who sees the fundus up to the moment the exposure is made. If it is impossible to get a clear image of the fundus, one of the auxiliary lenses, a +75, a +150, a -75 or a -150, which are in a revolving disc just beneath the shutter box, may be turned into position. By pressing the double shutter release, which in the illustration is seen lying on the compound slide, the spring action of

Fig 4—The Nordenson Camera, left side

little investigation few will admit that it is possible to have accurate descriptions of the fundus without a photograph. With eye ground pictures, we may compare the various portions of the fundus under varied conditions. For teaching and for study this method is incomparable. For the delineation of progressive fundus changes, no process has ever been devised that so completely fills the need as photography and stereo-photography.

We may then expect to see finer changes in their complete topographical relation to the details of the fundus in a photograph than we can by direct ophthalmoscopy. It must, however, be recalled that, just as the peripheral portions of the fundus are difficult to see with the ophthalmoscope, so they are with the camera, and as with the former instrument there is distortion, so there will be with the latter. It is, therefore, difficult to portray the changes in the extreme fundus periphery, and also impossible in a single picture to show all of the fundus. By changing the direction of the eye and the instrument, several pictures may be taken and placed together to build up the whole background.

This newer method will enable us to convince many patients and many physicians of the need of improving body hygiene and protecting blood vessels from undue muscle strain. It is possible to show the progress of many diseases toward recovery and also to record the retrogressive changes such as progressive optic atrophy. Further, we may by photographs differentiate between some chronic and some acute eye conditions, especially in the increasing class of compensation claims. The changes in the optic nerve following operation for brain tumor will prove to be so interesting that every large clinic devoting time and attention to this particular

special field will of necessity take photographs of the fundus before, after and during treatment, so that by this process a clearer conception of the various types of optic nerve changes brought about by increased intracranial pressure will be made known. To the internist the appeal should be great, for it will enable him to keep a record of unusual beauty and clearness. Photography of the fundus will prove of immense practical value to the progressive ophthalmologist. Many patients, particularly those suffering from disease, will be anxious to have pictures of their eye grounds. In medico-legal work fundus photography will assume an increasing value as time progresses. The criminologist will use these pictures for the recognition of delinquents, for the fundus is doubtless more characteristic than finger prints and cannot possibly be altered by external changes.

A true photograph shows things as they are and, this is frequently at variance with the interpretation that an ophthalmologist places upon things as he sees them. It must be recalled that, "Things are to the eye that sees them as to that eye they seem to be." A photograph removes the doubt as to whether a condition exists and is overlooked, for after a busy day the pictures are carefully reviewed and each fact properly evaluated.

Photographing the inside of the eye will open new channels of investigation, will make observation more accurate, and will assume a large rôle in ophthalmological advance in all branches of medicine, for the photographic records will stimulate all physicians to know more about the eye.

It is with pleasure I acknowledge the great technical skill and assistance given me by Mr. James A. Glenn in the development of the photographs.

*Plates 1 to 8, which appear on the succeeding pages, are reproduced from the photographs taken with the Mordenson camera*

illustrative groups are placed together in this monograph

### THE OPTIC NERVE

We will first speak of the optic nerve, which is often the only part of the fundus seen by a beginner. The outline varies from the clear, sharp edge without pigmentation, to a distinct encircling black ring. The disc varies in shape from round, to oval, to irregular, and in size from small, to very large. The nerve may be on the level with the retina, or portions of it may be elevated or depressed such as in colloid masses or retainted nerve sheath, or there may be a swelling and a protrusion of the entire nerve head as in choked disc. The central excavation demands special observation with notation as to its size, form, and depth. Although easily seen in the single photograph, the stereoscopic picture is necessary for its further study and appreciation.

The size, number, manner of division, and distribution of the disc blood vessels are individual. The accessory vessels, such as cilio-retinal arteries, are illustrated. The color of the nerve is easily compared, and a permanent record of progressive changes is best made by successive photographs. For the convenience of the student, reference is made to Plates 3 and 4, where various optic nerves are depicted.

### THE MACULAR REGION

The most important portion of the fundus physiologically is the macular region, which shows in a most marvelous manner. The dark oval area with its abundant encircling blood supply and the deeper, central depression is beautifully portrayed.

The course of the blood vessels and vessel wall changes may be clearly shown. Exudates are reproduced in their true relation to the surrounding parts.

Congenital anomalies of most portions of the fundus lend themselves to photography.

The usual picture is approximately 35 mm in diameter, but varies slightly depending primarily upon the type plate used in the camera. This fundus view is large enough to include the disc, the macular region, and a considerable area of the surrounding fundus.

### INTERPRETATION OF A FUNDUS PHOTOGRAPH

It is essential to become familiar with the details of the fundus as shown in a photograph. The color of the nerve is usually distinctive, paler than the rest of the fundus and usually definitely outlined. The retinal veins are darker and larger than the arteries. The macular region is darker than the remaining portion of the fundus. As all ophthalmologists know, reflexes from the retina vary in size, shape, and distribution.

With the ophthalmoscope, a slight change in the position of the patient's eye or the observer's head, moves the reflex and it is, therefore, not difficult to distinguish it from exudate or pathologic changes. It is absolutely necessary that the various reflexes seen in the photograph be understood before one attempts to read a picture, otherwise erroneous deductions will certainly be made. In the series of pictures here presented, the common forms of reflexes are all illustrated. In most photographs two bright circles will be found. These are the bright carbon points of the arc lamp. The larger circle is always the lower and, therefore, one may easily orientate the plate if the disc and macular region are in the field. If the fovea is not on the plate, or if only a sector of the fundus has been taken, or if the arc points are superimposed on the white optic nerve or on pale areas in the retina or choroid, the bright circles will not be seen in the picture.

### PATHOLOGICAL CONDITIONS

Interpretation of pathologic changes must depend upon the careful study of the optic nerve, its color, form and elevation, combined with the observation of the central excavation.

The fundus blood vessels must be studied in relation to their major branches especially observing the general distribution, the outline and patency of each vessel, distribution as to the subdivision and peri-macular arrangement, and the outline for tortuosities and compression, as well as for the peri-vascular reflexes, and for patency as in constricted lumen or complete closure.

Blood in the retina appears dark in the picture so that hemorrhages may be definitely outlined, and depending upon the density of the extravasation, as well as shape, a diagnosis of superficial or deep hemorrhage may be made.

Exudate as an isolated fleck or a massive white collection, such as in retinitis circinata, is to be noted by its true relations to the surrounding parts. Changes in the macular region, especially exudate and hole, may be recorded.

In this group of reproduced pictures with accompanying short clinical descriptions, we have drawn attention to the most common fundus changes. If the suggestions we have made are followed, any medical man, with the photograph before him, can make a probable diagnosis of the condition of the eye.

### ADVANTAGES OF A PHOTOGRAPH

The advantage of a photograph is that it is an exact reproduction of the object viewed, and may be made a permanent record. It is well known that a visual impression is more lasting and expressive than a word picture.

Little need be said regarding permanent record. The advantages of it are obvious, and after a

little investigation few will admit that it is possible to have accurate descriptions of the fundus without a photograph. With eye ground pictures, we may compare the various portions of the fundus under varied conditions. For teaching and for study this method is incomparable. For the delineation of progressive fundus changes, no process has ever been devised that so completely fills the need as photography and stereo-photography.

- 9 Clear nerve head with a hyperopia of one diopter in a young male Veins and arteries intertwined, but easily differentiated on close inspection
- 10 Amblyopia Corkscrew vein  $+1.75 \times 145^\circ$  V 7/200 A 32 year old patient who has always had poor vision Nerve negative
- 11 Corkscrew arteries Normal nerve head in a mixed astigmatism of  $-75 = +1.25 \times 90^\circ$  V 20/20 The veins contrast well by their blackened streaks
- 12 Very vascular disc without excavation Myopia  $-4.00 = -75 \times 180^\circ$  V 20/20
- 13 Large, broad veins with hyperopic astigmatism of half a diopter in a 30 year old woman V 20/20
- 14 Vascular disc  $-25 = 25 \times 105^\circ$  V 20/20+ 46 year old man
- 15 The veins are dark and contrast well with the narrow arteries Normal nerve with myopia of  $3.25 = 25 \times 180^\circ$  V 20/20+
- 16 Large vessels partly obscured by the thickened nerve head  $-50 = +1.00 \times 180^\circ$  V 20/15?
- 17 Pigmented temporal margin of an ovoid disc  $+1.75 = +50 \times 90^\circ$  V 20/15?
- 18 Heavily pigmented temporal margin of the disc in a mixed astigmatism of  $+75 = +1.25 \times 120^\circ$  V 20/30 Many old corneal opacities
- 19 Cilio-retinal vessel on a clearly outlined vascular disc in a 53 year old woman with  $+1.00 = 50 \times 90^\circ$  20/20+
- 20 Disc margins distinct Many vessels in a low astigmatism  $-50 \times 160^\circ$  V 20/20+
- 21 Large central excavation with projecting upper vessels and cilio-retinal artery in a 37 year old man Total refraction  $+1.00 = +1.00 \times 120^\circ$  V 20/15?
- 22 Another example of cilio-retinal vessels with large central excavation in a 22 year old man with a  $-1.50 = -50 \times 105^\circ$  V 20/15?
- 23 The nerve is clearly outlined with small excavation and large distended veins in a 15 year old boy with myopia of  $-1.50 -2.00 \times 15^\circ$  V 20/20
- 24 The superior artery is in front of the vein, whereas the inferior one is covered by the vein

PLATE 1

## PLATE 2

## OPTIC NERVES

1 Nerve showing large veins and sharply demarcated central depression in a 24 year old man with a hyperopic astigmatism of  $50 \times 15^\circ$  V 20/15

2 Disc showing a clear cut central excavation and the branching of the veins from the central trunk  $+75 = +75 \times 90^\circ$  V 20/15 A 57 year old male

3 Nerve with full veins, small excavation and clear outline in a 59 year old patient with a hyperopia of 275 V 20/15

4 Slightly pigmented temporal side nerve. Moderate sized excavation in a patient with hyperopic astigmatism

5 Large central excavation with a vessel that could be mistaken for cilio-retinal. 54 year old woman  $-100 = +175 \times 105^\circ$  V 20/20

6 Central excavation in a distinctly outlined nerve. Nasal margin elevated so that all the vessels coming from that side of the disc project forward before passing back to the retina. 62 year old patient  $-225 = -50 \times 105^\circ$  V 20/15

7 A large, central excavation not extending to the lamina, in a simple hyperopia  $+75D$  60 year old male

8 Large, central excavation, prominent nasal side of nerve head partially obscuring the blood vessels  $-200$  V 20/15

9 Very large central excavation extending to the margin of the disc. Vessels coming from the nasal side extend into the vitreous. No evidence of glaucoma  $-325 = -125 \times 165^\circ$  V 20/15

10 Photograph through a nuclear cataract in a 71 year old man. Large central excavation. Vision with  $-1100$  V 5/200

11 A typical temporal conus  $-575 = -50 \times 75^\circ$  V 20/20+

12 A temporal conus in a 51 year old patient. With  $-500 = -50 \times 105^\circ$  V 20/20+

13 Clearly outlined nerve head surrounded by areas of choroiditis with migrated pigment in a 59 year old woman with a myopia of  $-350 = -450 \times 40^\circ$  V 20/200. There are other atrophic areas in the choroid especially one large patch in the macular region.

14 Nerve with an irregular outline in a mixed astigmatism of  $-225 = 275 \times 75^\circ$  V 20/30. Diffuse lens opacities. The conus is most marked below.

15 A large staphyloma surrounding the superior and temporal side of the nerve in a patient with 22 diopters of myopia.

16 Large disc with nodular, translucent spheres on its surface, Drusen,  $+25 = +50 \times 90^\circ$  V 20/15.

17 Secondary optic atrophy following a luetic neuro-retinitis in a 50 year old patient.

18 Optic atrophy evident two months after fracture of the orbit. The disc is pale and the outline distinctly pigmented.

19 A pallid nerve with clear and distinct outline in a 22 year old male  $+50$  hyperopia V 20/15.

20 A clear and distinct nerve with central excavation and three cilio-retinal vessels in a 42 year old woman  $+100 \times 90^\circ$  V 20/15.

21 Tabetic atrophy in a 55 year old male. Vision 14/200. The nerve is white the outline distinct and the arteries thread-like.

22 Optic atrophy following embolism of the central artery. The picture was taken eight years after the loss of vision. The nerve is white, the arteries are small and the veins much reduced in size. No light perception. 48 year old man.

23 Nerve head in a retinitis pigmentosa with myopia of four diopters. Vision equal to 3/200. The secondary atrophy of the nerve is very evident.

24 Post-papillitic atrophy with obscured nerve margin and organized connective tissue over the disc.

PLATE 2

## PLATE 2

### OPTIC NERVES

1 Nerve showing large veins and sharply demarcated central depression in a 24 year old man with a hyperopic astigmatism of  $50 \times 15^\circ$  V 20/15

2 Disc showing a clear cut central excavation and the branching of the veins from the central trunk  $+75 = +75 \times 90^\circ$  V 20/15 A 57 year old male

3 Nerve with full veins, small excavation and clear outline in a 59 year old patient with a hyperopia of 2.75 V 20/15

4 Slightly pigmented temporal side nerve Moderate sized excavation in a patient with hyperopic astigmatism

5 Large central excavation with a vessel that could be mistaken for cilio-retinal .54 year old woman  $-1.00 = +1.75 \times 105^\circ$  V 20/20

6 Central excavation in a distinctly outlined nerve Nasal margin elevated so that all the vessels coming from that side of the disc project forward before passing back to the retina 62 year old patient  $-2.25 = -50 \times 105^\circ$  V 20/15

7 A large, central excavation not extending to the lamina, in a simple hyperopia  $+75D$  60 year old male

8 Large, central excavation, prominent nasal side of nerve head partially obscuring the blood vessels  $-2.00$  V 20/15

9 Very large central excavation extending to the margin of the disc Vessels coming from the nasal side extend into the vitreous No evidence of glaucoma  $-3.25 = -1.25 \times 165^\circ$  V 20/15

10 Photograph through a nuclear cataract in a 71 year old man Large central excavation Vision with  $-11.00$  V 5/200

11 A typical temporal conus  $-5.75 = -50 \times 75^\circ$  V 20/20+

12 A temporal conus in a 51 year old patient With  $-5.00 = -50 \times 105^\circ$  V 20/20+

13 Clearly outlined nerve head surrounded by areas of choroiditis with migrated pigment in a 59 year old woman with a myopia of  $-3.50 = -4.50 \times 40^\circ$  V 20/200 There are other atrophic areas in the choroid especially one large patch in the macular region

14 Nerve with an irregular outline in a mixed astigmatism of  $-2.25 = 2.75 \times 75^\circ$  V 20/30? Diffuse lens opacities The conus is most marked below

15 A large staphyloma surrounding the superior and temporal side of the nerve in a patient with 22 diopters of myopia

16 Large disc with nodular, translucent spheres on its surface, Drusen,  $+25 = +50 \times 90^\circ$  V 20/15?

17 Secondary optic atrophy following a luetic neuro-retinitis in a 50 year old patient

18 Optic atrophy evident two months after fracture of the orbit The disc is pale and the outline distinctly pigmented

19 A pallid nerve with clear and distinct outline in a 22 year old male  $+50$  hyperopia V 20/15

20 A clear and distinct nerve with central excavation and three cilio-retinal vessels in a 42 year old woman  $+1.00 \times 90^\circ$  V 20/15

21 Tabetic atrophy in a 55 year old male Vision 14/200 The nerve is white the outline distinct and the arteries thread-like

22 Optic atrophy following embolism of the central artery The picture was taken eight years after the loss of vision The nerve is white, the arteries are small and the veins much reduced in size No light perception 48 year old man

23 Nerve head in a retinitis pigmentosa with myopia of four diopters Vision equal to 3/200 The secondary atrophy of the nerve is very evident

24 Post-papillitic atrophy with obscured nerve margin and organized connective tissue over the disc

PLATE 3

## PLATE 3

## OPTIC ATROPHY, GLAUCOMA, RETINITIS

1 Normal fundus R E in a 21 year old man V 20/20 Total refractive error  $+1.00 \times 90^\circ$  Disc is clearly and distinctly outlined with a large central excavation The veins and arteries branch in a normal way and extend over the retina The macula is clearly outlined

2 Normal fundus in a 60 year old woman, with a moderate degree of mixed astigmatism and many opacities of the cornea Disc clearly outlined Vessels normal No central excavation Clear macular region

3 Normal R E fundus showing corkscrew artery which encircles the superior nasal vein Young adult with vision of 20/20

4 Optic atrophy L E V 2/200 The boy was struck by an automobile six years ago, as a result of which he had complete optic atrophy There were no external signs of injury Optic nerve white, margins sharply outlined, arteries slightly smaller than normal, veins of normal caliber, with water-silk retinal reflex

5 L E, a progressive optic atrophy, after a fracture of the orbit Pictures taken four weeks after the injury The clearly outlined nerve is white and the arteries constricted V 20/100

6 Optic atrophy following an automobile accident in which the only evidence of head injury was a small cut on the upper lid R E Vision 20/50 Patient a 23 year old woman The illustration shows a pale optic nerve with small arteries Field of vision is greatly contracted

7 Hereditary optic atrophy Leber's disease Patient has been under observation for the last ten years and there has been no change in his central or field vision He is 36 years old R E V 1/200 The atrophy of the nerve is very evident Disc is white with sharp out-

line The blood vessels are reduced in size and number

8 Tabetic optic atrophy L E V 2/200 The sight has been failing for the past 13 years in a 52 year old man Disc white with a large atrophic excavation and attenuated vessels

9 Optic atrophy from embolism of the central artery of the retina L E 26 year old woman The patient was seen 9 days after she suddenly lost her sight The retina was then edematous Now five years later, the nerve is white, the arteries extremely small, in many places completely obliterated, and discerned only as white threads The veins are of irregular caliber and also reduced in size The nerve head is white with faintly pigmented outline margin There is a definite hole in the macular region

10 Glaucoma R E 62 year old woman who has been blind for some time in her right eye Complete undermining excavation of the atrophic nerve

11 Luetic retinosis L E 23 year old male Bilateral involvement Vision with  $-4.00/3/200$  A typical picture of the type fundus described by the older authors as characteristic of congenital lues The markings of the retina are indistinct, the whole fundus appearing gray The optic nerve is dirty white, although retaining its sharp outline Arteries and veins very small and the peripheral branches not shown in the illustration seem to be completely obliterated The pigment is irregularly distributed in small specks

12 Retinitis pigmentosa (primary pigmentary retinosis) A 33 year old man who has always had poor sight Vision in the left eye 6/200,  $-3.50 = -1.00 \times 105^\circ$  V 20/30 Field contracted within the ten degree point The photograph taken to the nasal side shows the gray fundus the irregular bone corpuscle type of black pigment the gray faintly outlined optic nerve and the small retinal vessels

PLATE 4

## PLATE 4

CHOKED DISC, POST-PAPILLITIC ATROPHY, DRUSEN CONNECTIVE TISSUE VEIL,  
RETINITIS PROLIFERANS, NORMAL MACULA

1 Choked disc Brain tumor L E vision 20/20 in a 29 year old man Marked swelling of the nerve head with no hemorrhage or exudate but large veins and arteries

2 Choked disc in a 62 year old man with a strongly positive Wassermann It is impossible to even indefinitely outline the nerve head because of the extreme swelling The veins are enormously distended and both arteries and veins are frequently obscured in their course by the retinal edema Several flame-shaped hemorrhages give the impression of a radiating crown of blood streaks In the macular region, indistinctly shown in the picture, are several radiating lines of yellow-white exudate, the so-called macular star

3 Post-papillitic atrophy in a 29 year old woman with vision of 20/40 First seen in May, 1926, when she had eight diopters of swelling of the nerve head, with a picture very much like No 2 The photograph was taken in the latter part of 1926 In June, 1926, the patient was operated upon by the occipital route The tumor was not completely removed The illustration shows the decrease in number and size of both arteries and veins, also the white nerve and fine lines in the stretched retina

4 Post-papillitic atrophy L E of No 3 Vision 20/20 The patient had the same amount of nerve swelling as was found in the right eye previous to operation, and yet it is to be particularly noted that the destructive changes in the nerve head and surrounding retina are very much less than in the right, although the nerve is pale, the major trunks remain patent and the retinal striation, although marked, is not as great as in the right eye

5 Post-papillitic atrophy in the left eye of a 4 year old child Photograph was taken

under unusually trying conditions, the patient having been bedridden for several months, frequently unconscious and blind She was bolstered up before the instrument by three assistants and after many attempts several photographs were successfully taken The changes that have taken place in the nerve are very similar to those that have followed retrogression after operation, marked pallor of the nerve with decreased size of the blood vessels and overlying connective tissue

6 Drusen of the optic nerve Right eye of a 15 year old girl with corrected vision of 20/15 The Drusen forms the nasal margin of the nerve By noting the inferior nasal vein, it is easy to observe the degree of swelling in that part

7 A connective tissue veil over the nasal margin of the left nerve in a 44 year old man Vision 20/20+ This veil, which extends over the nasal vessels and also a considerable distance into the vitreous, is almost transparent and seems attached to the nerve

8 A thick prominent connective tissue veil in a young man of 20 with 20/20 vision

9 Retinitis proliferans The illustration shows a projecting white mass attached to the superior portion of the disc, the reduced caliber of arteries and veins, the white nerve head and the striation of exudate about the macular region The mass contains many capillary twigs

10 Macular reflex L E 7 year old colored boy, in which the complete peri-macular reflex accentuates the outline, size and position of the macula with the darker fovea The elevated retinal vessels are in marked relief Vision 20-20

PLATE 4

## PLATE 5

## CHOROIDITIS, RUPTURED CHOROID, HOLE IN MACULA

1 Active choroiditis in a 63 year old woman R E vision 2/200 The only discoverable etiological factor, diabetes Patient came in with a definite uveitis Media too clouded for any fundus detail After six weeks of diet and general body regulation, the photograph was taken The choroidal patch, yellowish-white, is elevated and surrounded by a clearing zone

2 Old choroiditis Patient was a 50 year old man from whom it was impossible to get any history of the beginning of his attack After a thorough search no etiological factor was uncovered The disc is well outlined and the areas of choroidal absorption with pigment migration are above and to the nasal side L E vision 20/30

3 Old choroiditis L E vision 2/200 A patch of atrophy with a little pigment migration to the temporal side of the nerve in a 14 year old girl Faint radiating lines in the overlying retina Photograph was taken two years after the first visit, since which time there has been no change in vision

4 Old choroiditis L E vision 20/100 in a 36 year old woman With  $-2.00 = -1.00 \times 75^\circ$  V 20/20 Under specific treatment the active lesion subsided The areas of pigmentation and atrophy indicate the extent of the process The retinal vessels pass over the lesion without alteration in course or character

5 Extensive old choroiditis R E vision 5/200 Woman 40 years of age With a  $-2.00 = -3.00 \times 120^\circ$  20/70 Known to have had the disease for 17 years Wassermann positive No change in fundus following prolonged treatment The irregular areas of pigment deposit, the decreased caliber of both arteries and veins, obscured optic nerve outline and pallor of nerve head, are all easily seen in the photograph

6 Choroiditis R E vision 1/200 unimproved 60 year old male In contrast to the preceding case, the vessels are only slightly changed in caliber and the nerve retaining its normal color is more definitely outlined Wassermann negative Constitutional evidence of tuberculosis—tuberculin reactions positive

7 High myopia with secondary choroidal degeneration and optic atrophy in a 44 year old man Vision 2/200 With  $-7.50$  10/200 Photograph is of the left eye so turned that the clear margins of the staphyloma are easily shown and the large choroidal vessels seen beneath the thin retina

8 High myopia with posterior staphyloma in a 49 year old man Vision 3/200 and  $-12.00 = -2.00 \times 160^\circ$  20/70 Photograph is of the left eye The optic nerve is completely surrounded by depressed atrophic choroid The arteries and veins are small and there is a considerable degree of secondary retinal atrophy

9 Degeneration of the macula L E V 8/200 A sharply circumscribed macular area of choroidal degeneration with pigment migration found in an 8 year old boy who gave a history of having had poor sight for years

10 Choroidal pigmentation and atrophy L E V 20/40 16 year old boy with bilateral choroidal changes Photographed two years after all active symptoms had subsided The only etiological factor was positive tuberculin reaction and his response to hygienic surroundings and old tuberculin subcutaneously injected Blood vessels of normal size, caliber and distribution The area of choroidal atrophy is surrounded by an irregular zone of pigment migration The remaining portions of the fundus are clear and distinct

11 Hole in the macula, following direct impact of a baseball in the right eye five years ago 21 year old boy The illustration shows the pale nerve, narrow arteries, marked retinal reflex and a heart-shaped punched out area in the macular region

12 Hole in the macula The right eye of a 14 year old boy who came under observation in his present condition when he was 7 years old It was impossible to get any history of a former injury This perfectly round macular hole is slightly obscured by a thin gray film of organized connective tissue Vision 12/200

PLATE 5

## PLATE 6

## DETACHMENT OF RETINA, TUBERCULOSIS, VESSEL CHANGES

1 Detachment of the retina The light is focused on the large separation in the right superior temporal region

2 The same as 1, with the disc focused on the plate This shows the light reflex from the prominent retinal bulge The man, 66 years of age, suddenly noticed a reduction in his vision, which was 2/200 with a sector of field loss

3 Detachment of the retina V 5/200 Almost complete detachment of the retina of the left eye showing the gray waving ridges with corresponding deep shadows The separation is seen above the nerve and the undulating mass is clearly outlined below The patient, 56 years old, has always been myopic and had lost the vision of her right eye as a result of retinal detachment

4 Detachment of the retina in the lower half of a highly myopic eye R E V with a  $-20.00 = -2.00 \times 180$  10/200 The patient, a 30 year old woman, has always had poor vision The illustration shows the indefinitely outlined optic nerve and surrounding staphyloma The prominent folds of the detached retina, the vessels overlying them, are in the lower field

5 Complete detachment of the retina in a 49 year old man who had always been very myopic The wrinkled retina is seen to the nasal side A large staphyloma surrounds the disc

6 Tuberculous choroiditis in a 55 year old man with active pulmonary tuberculosis The picture of the left eye shows in the periphery of the fundus many white areas, with fuzzy indefinite borders and a few fine hemorrhages near the atrophic spots V 8/200

7 Solitary tubercle of the choroid in a 13 year old girl, who presented with a large, prominent swelling in the macular region of the right eye Vision 3/200 The illustration shows the area of destroyed choroid in the macular region with pigmented temporal margin and elevated grayish white nasal edge The optic nerve is pale but sharply outlined and is partially covered by a thin gray sheet

8 Arterio-sclerosis R E in a 73 year old woman with a systolic blood pressure of 250 There is marked tortuosity of some of the smaller arteries, especially on the lower margin of the nerve, also a small area of yellowish exudate above the macular region Vision 20/20

9 Localized arterio-sclerosis R E in a 47 year old woman, with blood pressure of 165/100 The inferior branches of the central artery show peri-vascular changes and appear as white streaks over the lower portion of the nerve

10 Arterio-sclerosis R E in a 60 year old woman Systolic pressure 182 The arteries are tortuous and of irregular caliber Along the superior temporal branch are many flame-shaped hemorrhages appearing in the photograph as dark blotches

11 Chronic nephritis in a 62 year old woman Fundus shows many fine peri-vascular hemorrhages with a large mass of blood with several white areas of exudate in and below the macular region of the right eye Blood pressure 200/120

12 Thrombosis of the superior temporal vein in a 56 year old man with systolic pressure of 152 The photograph shows the dark masses of blood and the white areas of exudate in the region supplied by the superior temporal vessel

PLATE 6

## PLATE 7

RETINAL ARTERIO-SCLEROSIS, RETINITIS CIRCINATA, THROMBOSIS,  
RENAL RETINITIS

1 Arterio-sclerosis in a 72 year old woman with a systolic pressure of 220 and vision of 3/200 presented these typical disease changes, partial obliteration of arteries, tortuous veins, aneurysmal dilatation of veins where crossed by the stiffened arteries, and marked artheromatous changes

2 Arterio-sclerosis in a 70 year old woman with blood pressure of 180/98 Left eye vision 20/200 This shows a few scattered white flecks of exudate with extravasation of blood almost opposite the arc spot

3 Emphasizes the marked increase in vessel wall thickness with practically complete obliteration of its lumen Same patient as 2

4 Shows the tortuous superior temporal vein and fine flecks of exudate Same patient as 2 The hemorrhage has disappeared

5 Chronic nephritis in a 70 year old man with pressure of 190/110 Illustration of the left eye shows massive whitish exudate with a tendency to the formation of a ridge around the macula Left eye V 12/200

6 Albuminuric retinitis in a 69 year old patient with blood pressure 160/78 Right eye V 16/200 Lattice-like fluffy white exudate over which the retinal vessels can be traced

7 Retinitis circinata of the left eye in the patient from whom 6 was made This illustrates how impossible it is to include all the fundus in a single picture

8 Retinitis circinata The entire zone of infiltration surrounds the macular region as an elevated whitish mass over which large retinal vessels pass Pale center with pigmented area V 6/200

9 Albuminuric retinitis Hemorrhages in and about the macular region The white exudate seen in 6 is unchanged

10 Chronic nephritis in a 70 year old man with pressure 200/120 The right eye shows masses of whitish exudate, splotches of hemorrhage, slight compression of the veins and a clear nerve outline surrounded by choroidal degeneration V 1/200

11 Arterio-sclerosis, with thrombosis of the superior temporal vein, in a 46 year old patient Systolic pressure 172 Photograph shows a large extravasation of blood The pipestem white artery and several areas of white exudate There are many flame-shaped hemorrhages in the lower portion of the field

12 Chronic nephritis in a 46 year old man Pressure 180/100 The illustration of the right eye, taken twenty-four days before death, presents a typical picture of the nephritic changes in the retina and optic nerve The nerve head is swollen with indistinct margins The arteries are of irregular caliber, in places very tortuous The veins are distended and partly obscured by the edematous retina There are flame-shaped superficial hemorrhages and many areas of exudate

PLATE 7

## PLATE 7

RETINAL ARTERIO-SCLEROSIS, RETINITIS CIRCINATA, THROMBOSIS,  
RENAL RETINITIS

1 Arterio-sclerosis in a 72 year old woman with a systolic pressure of 220 and vision of 3/200 presented these typical disease changes, partial obliteration of arteries, tortuous veins, aneurysmal dilatation of veins where crossed by the stiffened arteries, and marked arteromatous changes

2 Arterio-sclerosis in a 70 year old woman with blood pressure of 180/98 Left eye vision 20/200 This shows a few scattered white flecks of exudate with extravasation of blood almost opposite the arc spot

3 Emphasizes the marked increase in vessel wall thickness with practically complete obliteration of its lumen Same patient as 2

4 Shows the tortuous superior temporal vein and fine flecks of exudate Same patient as 2 The hemorrhage has disappeared

5 Chronic nephritis in a 70 year old man with pressure of 190/110 Illustration of the left eye shows massive whitish exudate with a tendency to the formation of a ridge around the macula Left eye V 12/200

6 Albuminuric retinitis in a 69 year old patient with blood pressure 160/78 Right eye V 16/200 Lattice-like fluffy white exudate over which the retinal vessels can be traced

7 Retinitis circinata of the left eye in the patient from whom 6 was made This illustrates how impossible it is to include all the fundus in a single picture

8 Retinitis circinata The entire zone of infiltration surrounds the macular region as an elevated whitish mass over which large retinal vessels pass Pale center with pigmented area V 6/200

9 Albuminuric retinitis Hemorrhages in and about the macular region The white exudate seen in 6 is unchanged

10 Chronic nephritis in a 70 year old man with pressure 200/120 The right eye shows masses of whitish exudate, splotches of hemorrhage, slight compression of the veins and a clear nerve outline surrounded by choroidal degeneration V 1/200

11 Arterio-sclerosis, with thrombosis of the superior temporal vein, in a 46 year old patient Systolic pressure 172 Photograph shows a large extravasation of blood The pipestem white artery and several areas of white exudate There are many flame-shaped hemorrhages in the lower portion of the field

12 Chronic nephritis in a 46 year old man Pressure 180/100 The illustration of the right eye, taken twenty-four days before death, presents a typical picture of the nephritic changes in the retina and optic nerve The nerve head is swollen with indistinct margins The arteries are of irregular caliber, in places very tortuous The veins are distended and partly obscured by the edematous retina There are flame-shaped superficial hemorrhages and many areas of exudate

PLATE 7

## PLATE 8

## NORMAL FUNDUS, STEREOSCOPE PLATES

1 Normal fundus, clearly outlined nerve large central excavation, sharply differentiated dark veins and lighter arteries Macular region distinct A young lady of 28 V 20/15, Total refractive error  $+25 = +25 \times 75^\circ$

2 Stereoscopic pictures of a normal fundus in a 50 year old patient Total refraction  $-2.50 = +3.00 \times 105^\circ$  V 20/15

3 Absolute glaucoma Complete glaucoma cup with white nerve in a man 57 years of age who has been blind in that eye 17 years

4 Retinal exudate 46 year old woman who first noticed failing vision four weeks before the photograph was made V now 3/200 In and about the macular region, the retina is edematous with a white downy exudate

NOTE The last three illustrations are, as far as we know, the first stereoscopic fundus views presented for publication

The retina and optic nerve will be seen in true perspective if viewed through a stereoscope

PLATE 8

## PLATE 8

## NORMAL FUNDUS, STEREOSCOPE PLATES

1 Normal fundus, clearly outlined nerve large central excavation, sharply differentiated dark veins and lighter arteries. Macular region distinct. A young lady of 28. V 20/15, Total refractive error  $+25 = +25 \times 75^\circ$

2 Stereoscopic pictures of a normal fundus in a 50 year old patient. Total refraction  $-2.50 = +3.00 \times 105^\circ$  V 20/15

3 Absolute glaucoma. Complete glaucoma cup with white nerve in a man 57 years of age who has been blind in that eye 17 years

4 Retinal exudate. 46 year old woman who first noticed failing vision four weeks before the photograph was made. V now 3/200. In and about the macular region, the retina is edematous with a white downy exudate

NOTE. The last three illustrations are, as far as we know, the first stereoscopic fundus views presented for publication

The retina and optic nerve will be seen in true perspective if viewed through a stereoscope

## VACATIONS

The time of vacations is nearly over and most doctors are back at work. It is doubtful that any community has suffered because a considerable proportion of its doctors have been away from work, for most physicians take their leave of absence at a time when their practices are the least active.

Most physicians are glad to get back to their routine practice, for active work in one's chosen field is the desire of every normal person. No one is entirely idle while on a vacation, for

everyone golfs, or hikes, or fishes, or engages in some other form of strenuous activity. Yet it is not the activity which makes a vacation attractive, but it is the novelty of the change. And when the novelty wears off, as it does in a week or two, the desire for the old office and patients becomes overpowering and the return to duty is as happy as its relinquishment.

The best vacation is that which is taken piecemeal—an hour or two a day on the golf links, or in a speedboat, or engaged in some avocation which one cherishes from the pure love of it.

## BROADENING THE ACTIVITIES OF MEDICAL SOCIETIES

A quiet movement is taking place among the medical societies of New York State to broaden and unify their activities. There are three principal groups of medical societies:

- 1 County societies
- 2 Academies of Medicine and societies of specialists
- 3 Local societies

The automobile has annihilated space and has enabled rural physicians to attend meetings in the cities where Academies and specialists and local groups have flourished. The ease of transportation is restoring the County Medical Society to its former predominance.

The experience of Brooklyn demonstrates the possibility and desirability of unifying all medical societies in one organization. There the Kings County Medical Society fulfills all the functions of an Academy of Medicine. It maintains one of the largest medical libraries in the United States and dominates the entire public health field of Brooklyn. Societies of specialists

and local societies are feeders and supporters of the county society and depend on it for their literary facilities and carrying out their public health projects. There has never been any question regarding the dominance of the medical profession of Brooklyn by the Kings County Medical Society.

The physicians of the city of Watertown maintained a local medical society which held monthly meetings and gradually displaced the county society as the dominant society in Jefferson County. When automobile transportation became rapid and reliable, physicians from the rural communities drove in to the meetings until the City Society duplicated the membership of the County Society. The City Society then disbanded as a Society but transferred its activities to the county society, which now holds monthly meetings and controls all the public health work of Jefferson County.

The unification of medical organization in the county societies is a movement in the right direction.

## OPERATIVE AND SPECULATIVE MEDICINE

Systems of thought are divided into the operative or practical, and the speculative or theoretical. Medical authors attempt to reconcile these two systems when they name a textbook "The theory and practice of medicine", but any textbook or system of medicine will be largely speculative, and will prove to be deficient when it is tested at the bedside on an obscure case.

The general practitioner deals with operative medicine, just as the Salvation Army leader deals with operative religion. The people cry out "What shall we do to be saved?", and the general practitioner as well as the Salvation Army leader proceeds to do something tangible and practical without entering into the speculative aspects of the cases.

It is the duty of the doctor to make a diagnosis,—that is, a scientific classification of the sickness or disease,—for this is the basis on which he will apply his treatment. Dr Samuel Lambert says "Diagnosis is a working hypothesis for the application of therapeutics, subject to change without notice on the discovery of further evidence." Every doctor who prescribes a pill or a powder does so on the basis of a working hypothesis, whose correctness will depend on the doctor's scientific knowledge and experience. The successful doctor is the one who achieves a high degree of success in both speculative and operative medicine.

Public health and civic medicine have both their speculative and their operative aspects.

## PHOTOGRAPHS OF THE EYE FUNDUS

The ophthalmoscopic examination of the fundus of the eye is a procedure in which every practitioner of medicine should be trained, according to many practical teachers of medicine. A great difficulty in acquiring skill in making the examinations has been the lack of accurate pictures of the various conditions of the fundus both normal and abnormal, with which a learner may compare his own findings. That lack is now being supplied by actual photographs taken

of the interior of the eye with cameras specially made for the purpose.

The series of 115 photographs, which are published on page 957 of this issue, illustrate the value of this new method of recording the findings of the ophthalmoscope. These photographs were taken by Dr. Arthur J. Bedell of Albany and won for him the Lucien I. Howe prize. Every physician should preserve these photographs for reference and study.

# MEDICAL PROGRESS

**An Analysis of Ulcer of the Stomach and Duodenum.**—Ralph Lynch, writing in the *Canadian Medical Association Journal*, June, 1927, xvii, 6, presents an analysis of 944 cases of ulcer observed at the Montreal General Hospital during the ten-year period 1917 to 1926, inclusive. Of the 944 cases, 690, or 73 per cent, were in males, while 254, or 27 per cent, were in females, 541, or 57 per cent of the ulcers were duodenal, 380, or 40.6 per cent, were gastric, and 23, or 2.4 per cent, were peptic. Almost 100 per cent occurred in the white race. Fifty-seven per cent of the ulcers were found in persons between the ages of 30 and 50 years. Of the associated infections 8 per cent were dental, 3 per cent tonsillar, 0.6 per cent sinus, 2 per cent syphilitic, 1 per cent tuberculous, while carcinoma was found in 3, or 0.3 per cent. There was a history of typhoid fever in 10 per cent, of pneumonia in 7 per cent, of epidemic influenza in 5 per cent, of rheumatic fever in 0.3 per cent, of nephritis in 3 per cent, abdominal injury in 1.6 per cent and the use of alcohol in 23 per cent. The most frequent symptom was localized abdominal pain in 40 per cent. The x-rays gave positive evidence of ulcer in 40 per cent, suggestive evidence in 34 per cent and negative findings in 26 per cent. Gross hemorrhage was recorded in 52, or 5.5 per cent, of the cases, which is considerably lower than is usually given. Of the 52 cases, 31 were treated medically, with a mortality of 13 per cent, 21 were treated surgically with a mortality of 43 per cent. The result of the study of the medical treatment indicates that 62.5 per cent of gastric and 79.5 of duodenal ulcers respond to the Lenhartz or Sippy management. The Sippy method was used in the medical wards, and the author agrees with Alvarez in believing that frequent feeding, rather than alkalinization, is the point of importance. Many patients do well without alkalinization. The relief of symptoms that follows the institution of a dietary regime is scarcely less striking than the action of quinine in malaria. The failure to get relief from a standard system of diet should make the internist question his diagnosis, neurasthenia should be carefully excluded. If the case does not respond to dietary treatment, he should be convinced that there is an anatomical lesion (adhesions, gall-bladder disease, or the like) and that surgical consultation is indicated. In surgical cases operation should be postponed until bleeding has subsided and the patient's systemic condition has considerably

improved, usually four or five weeks after the subsidence of hemorrhage.

**Retention of Appetite and Bulimia in Cancer of the Stomach.**—P. Le Noir and R. Liege relate some personal experiences with this symptomatology which is seen exceptionally in cancer of the stomach and which may even coexist with pain and vomiting. In a woman aged 54 with a voluminous tumor of the stomach, found to be inoperable, the appetite which had at first failed, reappeared and the patient gained 27½ pounds in the five months which followed the exploratory laparotomy. Death took place in 11 months after this intervention. In another case reported at much greater length the patient was a man of 66 who had complained of his stomach for a year. Food relieved the pain of which he complained and far from having any aversion to meat he was particularly fond of it. During the year he had lost over 35 pounds. He had never vomited and in addition to the pain mentioned complained only of nausea and constipation. His appearance was that of a patient with cancer of stomach, pale and waxy. Local symptoms were absent with the exception of tenderness on pressure and muscular defence. An autopsy could not be obtained in this case but the positive roentgen finds, the emaciation, anemia, and cachexia were sufficient to uphold the diagnosis of cancer. This patient, in short, had hunger pains which were relieved by food and there were no evidences of failure of digestion. Bulimia in cancer of the stomach has been noted by Brinton, Deschamps (inaugural thesis, 1884—six cases), Arnozan, Hanot, Mathieu (numerous cases), Guillemard, M. G. Lyon, and Bourget. Owing to the great infrequency of this symptomatic type, the danger of making a fatal diagnostic error in cancer of the stomach with bulimia is to be borne in mind.—*Le Progres Médical*, June 25, 1927.

**Heredity in Cancer of the Stomach.**—V. Pauchet and A. Hirschberg contributed their findings toward the elucidation of this problem, which has recently come up in the sessions of the Académie de Médecine. The incidence of an hereditary factor has been placed at 6 to 16 per cent, 13 per cent, 15 per cent, and 5 per cent by as many authorities. The total material of the authors is 150 gastrectomized cases in which there was full opportunity for microscopic control. With respect to a possible bearing of heredity the authors make a distinction between the vege-

The public health nurse who discovers a case of rickets in a needy family seeks to apply operative medicine when she brings the case to a doctor and asks him to treat it. The doctor practices speculative medicine if the prospect of no pay impels him to decline to give the treatment.

Whenever two doctors are agreed on a diagnosis or working hypothesis, they readily agree on the therapeutics to be applied. When physicians and lay health workers are agreed on a diagnosis of a public health condition, they readily agree on the practical measures to apply

to the situation. Physicians in their individualism often lack the social point of view, while lay workers are prone to overlook the individualism of both the patients and the doctors. Neither group can afford to ignore or condemn the other.

The Committee on Public Relations of the Medical Society of the State of New York is accomplishing the great work of getting the physicians and lay workers to agree on a working hypothesis for the application of effective measures in public health and civic medicine.

## GRADUATE MEDICAL EDUCATION

There is no closed season for graduate medical education. Hundreds of physicians have attended clinics in Europe during the summer while their wives studied art in the great galleries located in the medical centers, while hundreds of others have combined pleasure with profit in attending clinics in Greater New York, Buffalo, and other clinical centers. But with the resump-

tion of work by the county medical societies, graduate medical education will be one of their principal activities.

The Committee on Public Health and Medical Education of the Medical Society of the State of New York will be ready to assist any county society that will undertake any line of graduate medical education.

## LOOKING BACKWARD THIS JOURNAL TWENTY-FIVE YEARS AGO

*Typhoid Not Always Water-borne* Epidemics of typhoid were considered to be almost entirely water-borne during the period of the Spanish War, and the years immediately following, but a commission of medical officers of the U S Army, appointed to investigate the prevalence of typhoid in the American Army camps reported adversely upon the water-borne theory. This report was the occasion of an editorial in this JOURNAL for September, 1902. After showing that civilians of several cities escaped typhoid although they drank the same water that the soldiers used, the editorial says:

"Failing to find in the water supplies a common cause for the widespread epidemics, the commission with greatest labor traced out and located every case of typhoid which had developed in a number of regiments. In this way 1,608 cases were investigated. All these cases were plotted out in charts, showing the tents in which they occurred and the dates of their occurrence. As a result of this investigation the commission came to this important conclusion: Typhoid fever, as it developed in the regimental organizations, was characterized by a series of company epidemics, each one having more or less perfectly its own individual characteristics."

"In 1,608 cases of typhoid fever which we have

been able to accurately locate in the particular tents in which they occurred, together with the date of the commencement of the attack, the results may be summarized as follows:

Directly connectable attacks	
(in same tent)	563, or 35.01 per cent
Indirectly connectable attacks	
(in next tent)	447, or 27.79 per cent
Total connectable attack	1,010, or 62.80 per cent "

The plan of getting a complete history of each case seems to have been novel at the time, but it is now the standard method that is used in every epidemiological investigation.

The editorial makes the following general comment on the conclusions of the commission:

"The evidence adduced is sufficient to make a very strong case for the verdict of the commission that the direct and indirect infection in tents were most important factors in the spread of the epidemics."

There is no hint of the part taken by flies as bearers of bacilli, or of the infection of food in the kitchens by food handlers. One reading the report will be surprised to learn how modern are present epidemiological methods.

In surgical cases operation should be postponed until bleeding has subsided and the patient's systemic condition has considerably

improved, usually four or five weeks after the subsidence of hemorrhage.

**Retention of Appetite and Bulimia in Cancer of the Stomach.**—P. Le Noir and R. Liège relate some personal experiences with this symptomatology which is seen exceptionally in cancer of the stomach and which may even coexist with pain and vomiting. In a woman aged 54 with a voluminous tumor of the stomach, found to be inoperable, the appetite which had at first failed, reappeared and the patient gained 27½ pounds in the five months which followed the exploratory laparotomy. Death took place in 11 months after this intervention. In another case reported at much greater length the patient was a man of 66 who had complained of his stomach for a year. Food relieved the pain of which he complained and far from having any aversion to meat he was particularly fond of it. During the year he had lost over 35 pounds. He had never vomited and in addition to the pain mentioned complained only of nausea and constipation. His appearance was that of a patient with cancer of stomach, pale and waxy. Local symptoms were absent with the exception of tenderness on pressure and muscular defence. An autopsy could not be obtained in this case but the positive roentgen finds, the emaciation, anemia, and cachexia were sufficient to uphold the diagnosis of cancer. This patient, in short, had hunger pains which were relieved by food and there were no evidences of failure of digestion. Bulimia in cancer of the stomach has been noted by Brinton, Deschamps (inaugural thesis, 1884—six cases), Arnozan, Hanot, Mathieu (numerous cases), Guillemard, M. G. Lyon, and Bourget. Owing to the great infrequency of this symptomatic type, the danger of making a fatal diagnostic error in cancer of the stomach with bulimia is to be borne in mind.—*Le Progrès Médical*, June 25, 1927.

**Heredity in Cancer of the Stomach.**—V. Pauchet and A. Hirschberg contributed their findings toward the elucidation of this problem, which has recently come up in the sessions of the Académie de Médecine. The incidence of an hereditary factor has been placed at 6 to 16 per cent, 13 per cent, 15 per cent, and 5 per cent by as many authorities. The total material of the authors is 150 gastrectomized cases in which there was full opportunity for microscopic control. With respect to a possible bearing of heredity the authors make a distinction between the vege-

tating and infiltrating stomach cancers. The total number of these patients with an hereditary or familial factor was at most seven, to which may be added one case in which the mother died of "abdominal cancer" and another in which the mother succumbed to cancer of the breast. The percentage then is but 6 at the outside, corresponding to the lowest figures of the authorities quoted. In six of the nine patients the cancer was of the vegetative type, in two of the infiltrative, and in the ninth the type was mixed. The history of heredity was present in all but one case and in that, in which the familial element was noted, there were two brothers with cancer of the stomach without a parental history. So far as the relatively small material justifies conclusions, the typical hereditary patient should be relatively young (under 55) when attacked and his cancer should be of the vegetating, pseudoglandular type. The authors call attention to the great difficulties inherent in this problem, for after the diagnosis of cancer in the actual patients is established, it is very difficult to determine the presence or absence of cancer in the ascendants.—*Bulletin de l'Académie de Médecine de Paris*, June 14, 1927

**Non-specific Protein Therapy of Chronic Joint Diseases**—P. Spiro refers to the treatment of arthritis and arthrosis by so-called stimulating non-specific treatment, which term the Germans use in preference to protein treatment, probably because a few of the substances used are not proteins. The author employed a variety of milk products as protein representatives and also a preparation of sulphur and gelatine, sulphur oil, etc. Radium emanation is also mentioned under this head. Sulphur preparations given parenterally were employed in the treatment of chronic arthritis and peri-arthritis by Meyer-Bisch. Aside from the above, little or nothing is said of the details of treatment. The results obtained thus far by the author are stated as follows: the number of cases of chronic infectious arthritis treated was 16, of which 9 were benefited and 7 unimproved. The number of cases of destructive peri-arthritis treated was 26, of which 10 were benefited. Osteoarthropathia deformans gave the least favorable results, for out of many treated (no total is given) but one reacted positively and the same may be said of osteoarthritis deformans. Of 11 cases of secondary chronic joint rheumatism treated, 9 were benefited, and of 14 cases of primary chronic polyarthritis, all but one responded. Of 18 cases of exudative arthritis all but one were treated with success and of 12 cases of adhesive arthritis 6 were benefited. Of 6 cases of ulcerated arthritis not one improved and but one good result was obtained in an unstated number of cases. The three types of deforming joint disease, all of which failed to benefit, are differentiated as follows. Deforming

osteoarthropathy is essentially dependent on faulty metabolism, deforming osteoarthritis is a trophic alteration, while deforming arthritis is characterized by new formation of bone.—*Deutsche medizinische Wochenschrift*, May 27, 1927

**Lymphogranulomatosis Inguinalis**—W. Frei of Breslau publishes a timely monographic article on this newly described affection which simulates chancroidal bubo, syphilis leucemia, and tuberculosis and concerning which widely varying statements have been published. Another very similar, if not identical, affection has recently been described under the name of poradenitis inguinalis, but the author does not repeat this name although he gives the references. The affection is certainly not new in the clinic, however it may be in literature, for it agrees in many respects with strumous or scrofulous bubo of old writers and perhaps has been masked in the past as *bubon d'emblé* in which it was supposed that a minimal chancroidal lesion on the penis had disappeared before the day of consultation. Increased prevalence of the disease in recent years has been variously explained but chiefly by importation from the tropics and subtropics. As is the case with poradenitis, no microorganism has been discovered in the fistulous discharge or punctate, and inoculation experiments on monkeys have chiefly proved negative. But inoculation experiments on the bearer have given positive reactions. Apparently every known affection which might simulate the one in question can be excluded by one or another test, including histological study and blood examinations. Positive results seem to have been seen under treatment with emetine, iodides, and antimony, also radiotherapy and non-specific protein injections. Excision, which should be the logical procedure, has not often been done for fear of setting up elephantiasis. There is clearly no ideal treatment as yet and probably will not be until the etiology is definitely established. Over fifty cases of this affection have been described in the past 18 months, in a few of which there was a history of sexual exposure and of a questionable transitory lesion on the penis, but this, however, is quite exceptional.—*Klinische Wochenschrift*, June 4, 1927

**Treatment of Hiccough**—Gaston Lyon discusses this subject quite thoroughly, taking up in succession the various clinical and etiological types. The most familiar of these is seen after hearty or hastily-eaten meals especially if highly spiced, and after alcoholic overindulgence. The first aid treatment consists in holding the breath, in slowly sipping cold water, plain or charged, or in sucking ice. Vomiting is doubtless indicated but an emetic would be too severe treatment for so mild a disorder. Should the hiccough fail to yield to these mild measures, cold or heat may be applied to the epigastrium with rhythmic tractions

on the tongue and compression of both phrenic nerves between the two insertions of the sternomastoid muscles. If the galvanic current is available the phrenic nerve may be galvanized. Of medicaments many sedatives and anti-spasmodics have been used, naturally those with the most prompt action first, as a few drops of ether or chloroform, but after the disorder has become inveterate opium, papaverine, belladonna, the bromides, etc. It is best to combine several of these remedies in one prescription. If the indigestion which is responsible for the symptom is characterized by hyperacidity, alkalies are indicated and the author believes that a combination of an alkali with a sedative is the best routine prescription, instancing a formula of bismuth carbonate, calcined magnesia, and powdered belladonna root. Hiccough accompanies a great variety of diseases in which it may be an unpleasant symptom and the treatment must of course be both causal and symptomatic.—*Le Bulletin Medical*, June 1-4, 1927

**The Heart of Malarial Subjects**—E. Benhamou and Marchioni of Algiers, internist and radiographer respectively, discuss in detail the so-called globular and flaccid heart of the chronic malarial subject, and arrive at the following conclusions. Malaria has an important action on the heart which is recognizable by serial radiography. The organ passes rapidly from the normal to the globular and flaccid type with soft and slow pulsation. By reason of its frequent occurrence it becomes a true stigma of chronic paludism. In examination of malarial patients by ordinary clinical methods we often find murmurs, edema, enlarged liver, ascitic and pleuritic transudations, and asystolia or hyposystolia—the clinical picture in fact of the globular and flabby heart. The pathological condition is not a myocarditis but a functional insufficiency from hypotonia. This condition may be produced by the cooperation of several factors—vagotonia, anemia, suprarenal insufficiency, and especially the accesses of intermittent fever. These patients require both quinine and digitalis.—*Archives des Maladies du Cœur*, June, 1927

**Application of the Principle of Quarantine in Abdominal Surgery**—Robert C Coffey has confirmed the experimental work of Yates which demonstrated that all the usual forms of drains used in abdominal surgery were closed, so that absolutely no drainage from the peritoneal cavity would take place, after six hours. He also agrees with Yates in condemning the usual forms of drainage of the peritoneal cavity on the ground that with them drainage is impossible, it is depleting, and pus and blood are not drained away. In order to overcome these objections Coffey has devised the quarantine drain, which possesses the following essential qualities: (1) The surface on the side of the peritoneal cavity is smooth and nonoffensive to the abdominal organ with which it

comes in contact. (2) It remains accurately in place. (3) It provides ample drainage and may be removed with the least possible trauma. The quarantine drain is made of strips of gauze five or six inches wide, cut across a 36-inch bolt of gauze. The ends of the wick are formed by the two selvage edges of the gauze. All the cut edges are accurately turned in and ironed with a flat iron and the wicks are twisted. The two ends are brought together and again twisted. Six of these double wicks are placed in a package and sterilized. When unfolded for use, the two ends of the wick are untwisted from each other, care being taken not to expose raw edges. When placed, each loop is laid separately, the middle of the loop being brought to the surface, where it is cut, thus leaving two wicks to be removed. Twelve wicks of this kind are sufficient for establishing and maintaining the quarantine and draining the area. These wicks are massed together at the surface and covered with four thicknesses of rubber tissue, making a drain about one-inch in diameter. The lower ends of the drain are spread out in fan shape to surround the area to be quarantined. The method of making the rubber tissue covering is described in detail. In a general way the indications for the use of such a drain are: (1) Infected organs which tend to produce a peritonitis by contact or discharge, (2) intra-abdominal abscesses so located that the wall is apposed to the neighboring viscera, and where the discharge must be conducted across the free peritoneal cavity after drainage is established, (3) an intra-abdominal viscus which, because of the presence of infection, or for other reason, it is impractical or undesirable to close at the time, (4) large denuded or bleeding areas which it is impossible to cover with peritoneum, (5) extensive recurrent adhesions which disturb the functions of abdominal organs.—*Annals of Surgery*, June, 1927, lxxv, 6

**Insulin in Septic Processes**—Dr H. Picard of the surgical university clinic of the Charité Hospital, Berlin, refers to the relationship between sepsis and the blood sugar content and to the fact that this content becomes increased in certain affections like furunculosis. Quite recently it has been shown that the power of insulin in reducing this content has a salutary effect on the disease. At the Charité clinic insulin has been employed in various suppurative affections—furuncle and carbuncle, abscesses of all kinds, felons, osteomyelitis, etc. Other and aseptic material was used as control, and in this group the blood-sugar content did not go above 100 mgm, while in the septic group the figure was invariably higher, with the exception of osteomyelitis, going from 120 mgm as a minimum to 215 mgm in a facial abscess. Insulin brought these figures down notably—in the facial abscess case to 135 mgm and in the others proportionally, but this fall was only temporary and

was succeeded in 24 to 48 hours by a rise. The clinical improvement however was not only more striking in character but seems to have been maintained, and some of the more impressive results were seen in chronic cases, e.g. furunculosis of 18 months' standing. Of great value was insulin in those furuncles of the lip which are often the odium of surgery. Advancing phlegmons were brought to a halt and in no group of these suppurations is there any mention of negative results, with the one exception of osteomyelitis, in which, as has already been mentioned, the blood-sugar content of the blood is not raised. This exception then is what one would expect, and insulin should be given in theory only after a blood test — *Deutsche medizinische Wochenschrift*, June 24, 1927.

**Diathermy in the Treatment of Pneumonia** — R. P. Forbes, writing in the *Archives of Pediatrics*, June, 1927 (xliv, 6), reports an encouraging experience with diathermy in the treatment of pneumonia in infants and children. Although this form of treatment was undertaken with considerable skepticism, it soon became evident that definite therapeutic results were being obtained. In 117 cases of lobar pneumonia in which diathermy was not employed, the mortality in the past three years was 28.2 per cent, as compared to 15.1 per cent in 33 cases of lobar pneumonia in which diathermy was used. In 190 cases of bronchopneumonia, in which diathermy was not applied, the mortality was 38.9 per cent, as compared to 19 per cent in a series of 63 patients receiving diathermy treatment. Although the duration of the disease was apparently unaffected, the percentage of complications of pneumonia was strikingly less in the series of patients receiving diathermy. In one patient in whom the r-rays showed an enlarged thymus and beginning pneumonia, diathermy apparently caused a rise in temperature, increase of cyanosis, and increase in pulse rate and restlessness. Myocarditis developed and death occurred on the thirteenth day. Whether the treatment was responsible for the thymus congestion is a matter of conjecture, but the experience suggests that thymus hypertrophy may be a possible contraindication for diathermy treatment of pneumonia. In a severe case of whooping-cough pneumonia in a young infant, in which a fatal termination would ordinarily have been expected, diathermy appeared to be life-saving. Forbes concludes that this form of therapy should be considered a valuable adjuvant in the treatment of pneumonia.

**Treatment of Whooping Cough in the Allergy-free Chamber** — W. Storm van Leeuwen

and W. Kremer of the University Clinic for Allergic Diseases at Leyden have extended the use of their allergic chamber to patients with whooping cough. Originally it was devoted to asthma cases. The room is so constructed as to exclude from the air all possibility of allergic substances. The material of the walls, etc., is a form of asbestos and the space is air tight. The furniture is of iron. The bedding is sterilized, and all the air that is allowed to enter the room is sterile and free from dust. The patients enter the chamber and remain until all attacks have ceased. No other treatment is employed. Five severe cases of pertussis were first treated. The ages of the patients were 14 months to 6 years, the day of disease the 16th to the 23rd. The first general result noted was the disappearance of all severe attacks, the mild attacks which persisted gave but little trouble and soon vanished. Two patients continued to vomit with their paroxysms for several days. The first patient left the chamber on the eighth day, the second on the sixth, day, although attacks ceased on the fourth day, the third on the fourth day, the fourth on the sixth day, and the fifth on the fifth day. The average sojourn then was but six days. Hence, thus far, the new method appears to be excellent to bring cases of two to three weeks' standing to a rapid arrest and cure—a great improvement over the usual methods — *Muenchener medizinische Wochenschrift*, May 27, 1927.

**Tetanus Following Intramuscular Injection of Quinine** — Four fatal cases of tetanus following the intramuscular injection of a solution of quinine bishydrochloride into the buttocks are reported by John Macqueen. In all of these cases the incubation periods were long: in two cases 27 to 28 days, in one 21, and in one 11 to 12. The illnesses, on the other hand, were usually severe, the time between onset of symptoms and death being in no case more than 72 hours. It was concluded that in all four cases the tetanus spores were introduced at injection. There did not appear to have been any obvious defect in the manner of preparation of the skin, the technique of injection, the sterilization of syringes and needles, or the preparation and sterilization of the solution. These cases serve as a reminder that quinine solution causes necrosis of the muscle-tissue and that necrosed tissue shut off from the air may form an ideal nursery for tetanus spores if they happen to gain entrance. They provide a further argument in favor of the oral as compared with the intramuscular route for the administration of quinine whenever possible — *The Lancet*, June 18, 1927, ccxii, 5416.

## WITH SABRE AND SCALPEL

One of the writer's favorite diversions is rummaging in old book stores. While thus engaged he came upon a volume which he bought, took home and could not put down until he read it through. It is the autobiography of an outstanding surgeon, a brave soldier and a fine citizen.

The book in question bears the interesting and appropriate title "With Sabre and Scalpel." It was written by the late Dr. John Allan Wyeth. There is no part of it that is not vital with interest and inspiration. It is the story of a southern boy who bore arms as a soldier in the Confederate Army, and who came later to New York City to write his name indelibly in the annals of medicine.

Dr. Wyeth was born at Missionary Station, Marshall County, Alabama, on May 26th, 1845, a descendant of Welsh, Scotch, English and German ancestors, and whose grandfathers on each side fought in the Revolutionary War.

Young Wyeth was but sixteen years old when the war between the States broke out. His father opposed secession in 1861, but when the convention of Alabama voted to join the Southern Confederacy, he gave himself to the cause, and although over legal military age, volunteered and served at the front until discharged on account of illness. Young Wyeth was graduated from the famous old LaGrange Military Academy, now but a memory as its buildings were destroyed by Sherman's army. The young man served first in 1862 with a company of Partisan Rangers and Quirk's Scouts of Morgan's Cavalry. The story of his exploits reads like a page of some old novel.

He served later in a regiment which was christened "Russell's Fourth Alabama" in honor of a "brave, grim doctor who laid aside the spatula and scalpel for the sword and six-shooter."

The chapters devoted to his military service in the Army of the Confederacy are thrilling. Among other great engagements in which he participated was the battle of Chickamauga, which marked the high-tide of the Southern Confederacy.

Just before the battle of Chattanooga, his troop was halted one afternoon at four o'clock when word came from the front down the line repeated from regiment to regiment, that "a volunteer was wanted at the head of the column who would go where he was ordered." Young Wyeth volunteered. When he reported to the general in com-

mand, he was asked "Are you willing to go inside the enemy's lines?" to which the young trooper answered "If it was necessary I would try to do what was required, provided I could wear my uniform, but that I wouldn't go as a spy." His services were accepted, and then at the dead of night, stripping his horse and himself of everything not absolutely necessary, and with no equipment save a small New Testament which his mother had handed him when he left home, and with a trusty army six-shooter, he went off on his dangerous mission. The mission was stated by his commanding officer in these words, "I want you to carry a message to some troops that have passed around their flank (McCook's Corps), and are now coming up in their rear. It is important that they be headed off and ordered to return by the route they traveled. To reach them in time you will have to pass through the Federal lines." Alone this boy of eighteen started off.

"It goes without saying," he writes, "that I appreciated the dangers which this mission involved, but the most astonishing feature of the psychology of this moment was that I found myself in a condition of mind in which the value of life became a secondary consideration. It had never come to me before, it never has since. In that brief period the stars were not far away, for I had eliminated self. The one absorbing thought which took possession of me was that my mother would be proud of me for trying to do my duty. I did not intend to be stopped, and with a swift, game and powerful horse the chances were in my favor." The young trooper rode through the Federal lines, delivered his message and accomplished fully the mission he had taken.

Later, he was captured, and was in nearly two years in a Federal prison. His sufferings there were far more than anything he had endured while in the Confederate service. Reports, "and to my surprise," he was captured by me. I was invited to the court-martial, so far as I am concerned.

## WITH SABRE AND SCALPEL

One of the writer's favorite diversions is rummaging in old book stores. While thus engaged he came upon a volume which he bought, took home and could not put down until he read it through. It is the autobiography of an outstanding surgeon, a brave soldier and a fine citizen.

The book in question bears the interesting and appropriate title "With Sabre and Scalpel." It was written by the late Dr. John Allan Wyeth. There is no part of it that is not vital with interest and inspiration. It is the story of a southern boy who bore arms as a soldier in the Confederate Army, and who came later to New York City to write his name indelibly in the annals of medicine.

Dr. Wyeth was born at Missionary Station, Marshall County, Alabama, on May 26th, 1845, a descendant of Welsh, Scotch, English and German ancestors, and whose grandfathers on each side fought in the Revolutionary War.

Young Wyeth was but sixteen years old when the war between the States broke out. His father opposed secession in 1861, but when the convention of Alabama voted to join the Southern Confederacy, he gave himself to the cause, and although over legal military age, volunteered and served at the front until discharged on account of illness. Young Wyeth was graduated from the famous old LaGrange Military Academy, now but a memory as its buildings were destroyed by Sherman's army. The young man served first in 1862 with a company of Partisan Rangers and Quirk's Scouts of Morgan's Cavalry. The story of his exploits reads like a page of some old novel.

He served later in a regiment which was christened "Russell's Fourth Alabama" in honor of a "brave, grim doctor who laid aside the spatula and scalpel for the sword and six-shooter."

The chapters devoted to his military service in the Army of the Confederacy are thrilling. Among other great engagements in which he participated was the battle of Chickamauga, which marked the high-tide of the Southern Confederacy.

Just before the battle of Chattanooga, his troop was halted one afternoon at four o'clock when word came from the front down the line repeated from regiment to regiment, that "a volunteer was wanted at the head of the column who would go where he was ordered." Young Wyeth volunteered. When he reported to the general in com-

mand, he was asked "Are you willing to go inside the enemy's lines?" to which the young trooper answered "If it was necessary I would try to do what was required, provided I could wear my uniform, but that I wouldn't go as a spy." His services were accepted, and then at the dead of night, stripping his horse and himself of everything not absolutely necessary, and with no equipment save a small New Testament which his mother had handed him when he left home, and with a trusty army six-shooter, he went off on his dangerous mission. The mission was stated by his commanding officer in these words, "I want you to carry a message to some troops that have passed around their flank (McCook's Corps), and are now coming up in their rear. It is important that they be headed off and ordered to return by the route they traveled. To reach them in time you will have to pass through the Federal lines." Alone this boy of eighteen started off.

"It goes without saying," he writes, "that I appreciated the dangers which this mission involved, but the most astonishing feature of the psychology of this moment was that I found myself in a condition of mind in which the value of life became a secondary consideration. It had never come to me before, it never has since. In that brief period the stars were not far away, for I had eliminated self. The one absorbing thought which took possession of me was that my mother would be proud of me for trying to do my duty. I did not intend to be stopped, and with a swift, game and powerful horse the chances were in my favor." The young trooper rode through the Federal lines, delivered his message and accomplished fully the mission he had undertaken.

Later, he was captured, and was confined for nearly two years in a Federal military prison. His sufferings there were far greater than anything he had endured while in the field. "All the rats which could be trapped were eaten," he reports, "and to my knowledge one fat dog was captured by my messmates, cooked and eaten. I was invited to partake, and, although the scent of the cooking meat was tempting, I could not so far overcome my repugnance to this animal as an article of diet as to taste it."

In 1864, his uncle, a Northern man, offered to secure his parole from President Lincoln and invited him to come and live with him and

tinue his studies in the University of Illinois "As the acceptance of this parole until the war was over would carry the implication of desertion in case an exchange of prisoners took place," wrote Wyeth, "I felt bound to decline the generous offer. My uncle then endeavored to have the parole modified so that I might remain until exchanged, but Mr. Stanton would not consent to this. It was a great temptation, but the last words my mother and father had said to me were, 'Don't forget that although you are only a boy, and all we have, we would rather have you come home in a coffin than dishonored.'"

Finally the war ended, and young Wyeth then took up the study of medicine in what was then one of the oldest and deservedly best known of the medical colleges in the United States—the medical department of the University of Louisville. No preliminary or entrance examination was required, and any white male who could read and write and who had mastered the rudiments of English was eligible. Neither Latin nor Greek was essential. The requirements for graduation were a satisfactory examination at the end of two college terms of seven months each.

The division of subjects was anatomy, physiology, surgery, medicine, obstetrics, chemistry and materia medica. Anatomy was thoroughly taught, and the didactic course was supplemented by dissecting-room work of a high order, although material was never overabundant. In physiology there were no laboratory exercises, no practical demonstrations of the living structures and of the functions of the normal organs. The teaching of surgery and medicine was almost wholly didactic. When an operative clinic was given, the students witnessed it at such distance from the subject and with so many interruptions of vision that it was impossible to follow closely the details of technique, without which the lesson of a demonstration is valueless. Not once during his two college years did the aspiring young medical student enter a ward of a hospital or receive instructions by the bedside of a patient.

Some indication of the character of medical teaching then in vogue is evidenced by the fact that the students were told "that the cause of malarial and yellow fever was a miasm emanating from decaying vegetable matter subjected to a temperature of from eighty to ninety degrees Fahrenheit for about thirty days, and that those who slept upon the ground floors of buildings suffered most, while those who occupied the second, third and higher floors escaped the baneful effects in the direct ratio of their elevation." "Knowing as we do now that the mosquito is not prone to fly high, that he infests the lower floors of houses, seldom reaching the third or fourth floor," says Dr. Wyeth, "we can understand readily the error in etiology on the part of our professor of medicine."

The teaching of obstetrics was entirely didactic. "In my two terms of study," the author says, "I examined only one gynecological case, while in chemistry and materia medica the instruction was in the lecture-room to the whole class instead of with working sections in the laboratory, and there was no course of study in microscopy or urinary analysis."

In the spring of 1869, young Wyeth was graduated from the medical school, and awarded a diploma. "The possessor of a pair of doctor's saddle-bags," he writes, "which held two rows of medicine bottles, diminutive apothecary scales for weighing dosage, two forceps for extracting teeth, and a small minor surgical operating set of instruments, and last, but not least, a tin sign, I rented an office in my home town of Guntersville, Alabama, and after dark one night in March, 1869, I tacked my sign to 'the outer wall.'"

It was not long before the young doctor concluded that he needed a clinical and laboratory training under teachers of experience, and determined temporarily to abandon his profession until he could secure that training, and so two months after he had tacked it up, he took down his sign and put it in his trunk where it reposed for several years.

In order to obtain the means with which to pursue his further studies, he went into the contracting business, and was engaged until 1872 in this activity "chiefly in transporting materials in public works." His chapter devoted to his experiences in Arkansas is highly entertaining and gives a picture of the life in that state at that time, which is of real historical value.

In 1872, having made a little money and being thus in a position to pursue his studies, he made a survey of the medical schools of the City of New York, and to his great surprise and disappointment, found that there were no special courses for graduates, and therefore "as clinical experience and practical anatomy were the chief attractions for me, I selected Bellevue College as offering the best advantages, and matriculated there in November, 1872." Almost at once he attracted attention as he there came under the leadership of Dr. Edward G. Janeway, who was then the demonstrator of anatomy. Under his guidance, in 1875, Dr. Wyeth took up the study of pathology. At this time he became well acquainted also with Dr. Abraham Jacobi.

It was not long before the young post-graduate was making independent researches of great value, and so between 1875 and 1878 we find him making careful investigations, beginning his work upon the carotid artery. The accepted teaching of that day, as expounded at a lecture by Professor Frank R. Hamilton, was that the branches of the carotid artery "were so irregular in origin and arrangement, and often so close together, that a ligature should never be applied to it,

that it seemed to be an exception to the general law of development of the arterial system in man," and that "the common carotid should be tied for all lesions in the distribution of the external branch" The young physician, hearing this lecture went away saying to himself, "It can't be so, and I must prove it" In 1878 he had done so, and as a result of his researches demonstrated "that these vessels obeyed a law as fixed as that of the other arteries, and that the common trunk should never be ligated on account of a lesion in the distribution of the external carotid"

The paper which he wrote upon this subject was offered in competition for one of the two prizes to be given by the American Medical Association at the meeting in Buffalo in 1878 Dr Wyeth won both prizes

Later his contributions to medical literature were numerous, and all of them of great scientific value Some of his medical contributions were "Bloodless Amputation at the Hip-Joint and at the Shoulder," "The Treatment of Vascular Tumors (Angiomata) by the Injection into their Substance of Water at a High Temperature," "Demonstration by Experimental Studies on Animals and by Operations on Human Beings of the Process of Permanent Arterial Occlusion after Deligation," and many others

Dr Wyeth was elected in 1886 President of the New York Pathological Society, in 1893 Vice-President of the American Medical Association, in 1900 President of the New York State Medical Association, and in 1901 President of the American Medical Association

There seemed almost a limitless capacity for endeavor in this full life Not only did he make many and important contributions to medical literature, but he also contributed numerous articles to the lay press among which were those entitled "Cold Cheer at Camp Morton," a narrative of prison life from October, 1863, to February, 1865, "Nathaniel J Wyeth and the Struggle in Oregon," "General Wheeler's Leap," "The Capture of Colonel A D Straight and His Entire Command," "The Storming of Fort Pillow," and many others In 1899 he published a "Life of General Nathan Bedford Forrest," and eight years later a "History of the LaGrange Military Academy and the Cadet Corps"

Among the lay honors to which Dr Wyeth attained was the Presidency of the Southern Society, and the Chairmanship of the Executive Committee of the Union League Club, inconsistent as these two positions would appear to be In this connection he tells of his admission to that dignified old Club on 39th Street so famed for its loyalty to the Union and to the Republican party "As the time for voting on my candidacy came near," he writes, "it occurred to me that an ex-Confederate soldier, whose natural leaning and training had been about as far away from what

the Union League Club represented as it could be, could never possibly be elected unless it were under a misapprehension" So he wrote to the Chairman of the Admission Committee that he had been reared in the South, and had served in the Confederate Army, and with the exception of the Bryan years, had always voted the Democratic ticket This letter was read aloud to the Committee, and the Chairman thereupon remarked "with a good deal of feeling that the Union League Club needed in its membership a Confederate soldier who could write such a letter, which sentiments the President indorsed," and he was unanimously elected

In 1881, the founding of the New York Polyclinic Medical School and Hospital "marked the introduction of systematic post-graduate medical instruction in America," and was "at least an important factor in the great movement which, starting at that period, has revolutionized and carried to a degree approaching perfection the teaching and practice of medicine and surgery in the United States" It was due largely to the efforts of Dr Wyeth that the organization of the Polyclinic as a post-graduate school was effected

Through the efforts of Dr Wyeth, together with the assistance of such philanthropists as Mrs Helen Hartley Jenkins and Mr William P Clyde, the splendid new building at 341-51 West 50th Street became a reality "I have always had an abiding faith in the ultimate triumph of a good cause," says Dr Wyeth "The only real setback to this conviction was the failure to establish the Southern Confederacy Now, the Polyclinic Hospital with its ambulance service differs from the Southern Confederacy in one important particular—viz, it is established"

But perhaps the most interesting chapter of all is that devoted to the division and re-union of the medical profession of New York State, which we shall make the subject of a further editorial

"With Sabre and Scalpel" is a record of a great life It must have been a great and versatile character who could rise through war and peace to the pinnacle of his profession, and who at the same time possessed that sensitive sympathy and feeling that enabled him to write these moving lines

#### "TO MY MOTHER

Deal gently with her, Time! These many years  
Of life have brought more smiles with them than  
tears

Lay not thy hand too harshly on her now,  
But trace decline so slowly on her brow  
That, like a sunset of the northern clime,  
Where twilight lingers in the summer-time,  
And fades at last into the silent night,  
Ere one may note the passing of the light,  
So may she pass—since 'tis the common lot—  
As one who, resting, sleeps, and knows it not "

# NEWS NOTES

## ERIE COUNTY MEDICAL SOCIETY

More than one hundred physicians in Western New York responded to an invitation to attend the annual outing of the Medical Society of the County of Erie, held June 23rd, on the spacious grounds of Gowanda State Hospital.

The physicians had been urged by the officers of the Society to lay aside their professional cares for the day, bring their families, and enjoy an old-fashioned basket picnic, with a program of sports and scientific talks.

The medical societies of Niagara, Chautauqua and Cattaraugus counties were well represented.

Dr Harry A. Trick, President-elect of the State Medical Society, addressed the gathering.

The medical staff of the State institution presented an instructive program, including a talk on the proper method of committing a mental patient, a demonstration of the results obtained in the treatment of general paralysis by inoculation with the malaria parasite, and an exhibition of the occupational and physical therapy departments of the hospital.

EDGAR P. ORVIS, M.D., *Secretary*

## THE AMERICAN COLLEGE OF SURGEONS

The American College of Surgeons will hold the seventeenth Clinical Congress in Detroit, October 3-7. Headquarters will be at the Book-Cadillac and Statler hotels, and the meetings will be held at the Statler Hotel, and Orchestra Hall. The Hospital Standardization Conference will extend from Monday morning to Thursday afternoon.

Clinics in general surgery will be held in the Detroit hospitals each morning from Tuesday to Friday, and in Eye, Ear, Nose and Throat work the same afternoons. Clinics will also be held at University Hospital, Ann Arbor, Tuesday

to Thursday. On Tuesday and Wednesday mornings and afternoons, and on Thursday morning, clinical demonstrations will be held at the Statler Hotel (mornings) and Orchestra Hall (afternoon). On Tuesday evening the program will take the form of a celebration of the Lister Centennial. There will be a replica of the Lister exhibit at the Wellcome Museum of Natural History, London, including Lister's operating rooms and hospital wards. The Departments of Hospital Activities, of Literary Research, and of Clinical Research of the College will also present exhibits.

## CONNECTICUT STATE MEDICAL SOCIETY CLINICAL CONGRESS

The Connecticut State Medical Society holds a clinical congress in addition to its annual meeting. The Congress this year will be held on September 20, 21, 22, in New Haven, in the Sprague Memorial Hall. One of the dormitories of Yale University will be set aside for the entertainment of the doctors. Dinner meetings will be held on Tuesday and Wednesday afternoons

at the Lawn Club, Whitney Avenue and Sachem Street. A fee of \$5.00 is charged which includes admission to all sessions of the Congress, and a copy of the abstracted papers presented. The program includes twenty-one papers on a wide range of subjects, including drug rashes, Cæsarean section, socialization of medical practice, common foot conditions, and asthma.

## DOCTOR CHARLES C. DURYEE

Dr Charles C. Duryee, of Schenectady, consultant in City Health Administration for the State Department of Health, resigned his position on the first of July and retired from active service.

He was one of the eight sanitary supervisors who were appointed by the Commissioner of Health Dr. Herman M. Biggs, on the reorganization of the Department of Health in

1914. He was always sympathetic toward the doctors and understood their point of view. He cooperated with the Albany Medical College in conducting a series of classes for the training of health officers, in which about 200 physicians have received instruction.

After 46 years of the practice of medicine and public health, Dr. Duryee retires honored and respected by the physicians of New York State.

# THE DAILY PRESS

## RESEARCH BY PRACTISING PHYSICIANS

One object of this department of Daily Press is to enable the editors to make comments on topics which they would not have the temerity to bring up if some prominent laymen did not introduce the subject

An editorial writer in the *New York Herald-Tribune* for August 15, brought up the subject of cooperative research by practising physicians, and makes the suggestion that "It ought to be a requirement of the world's intellectual by-laws that every man and woman who has brains enough to put one fact after another be compelled at least once a week to tackle some bit of original investigation" The occasion for the suggestion was the recent action of the British Medical Association in which "It was agreed that the general medical practitioners who belong to the Association shall be urged to join in cooperative scientific investigations"

Commenting on this action the editorial writer says

"Some one seems to have had the revolutionary idea that perhaps the ordinary doctor has quite enough sense to be worth using if only he could be introduced to tasks which will not too greatly overtax his time There are about thirty thousand of these doctors in Great Britain The Association purposes to enlist them in scientific endeavors in which each can do his bit, and all together can do much

"This is called a scientific age, and so it is if one notices nothing but the accomplishments of professionals We hire scientific men as we hire carpenters or ditch diggers, to do tasks which we are too lazy or unskillful to work at for ourselves Considered as a device to make money or to wage war or to lift the standard of living, this idea of the tame scientist works well The professional researchers are worth all that they cost But they cheat the rest of us of discipline The tasks of observation, of reasoning,

of experiment, which we assign to them would be good for everybody"

The editorial writer is correct in urging the desirability and value of research by professional men, but he seems to be unaware that the suggestion of the British Medical Association is far from revolutionary, but is as old as medical organizations themselves One of the great objects that was sought when the Medical Society of the State of New York was formed over one hundred years ago was that of investigating the causes of prevalence of diseases, and this year the Society took up the special investigation of heart diseases

It is a fundamental principle in the organization of the State and County Medical societies that every member is expected to be not merely the recipient of information and other benefits, but to contribute the record of his own experience to a common fund of medical knowledge Not only should he express his opinions on medical topics, but he is expected to search out and arrange the facts of his experiences in support of his opinions The duties of research and statement of his findings are preached by officers of his societies until the members are sometimes annoyed Why are the evidences of their response not more striking? The answer is that research and analysis on the part of physicians is so common that it is not news Only the unusual is news The newspaper editors and the people generally soon tire of the continuous record of the slow advancement of medical affairs in their midst, but once a year, or once in ten years, they suddenly discover that people are living longer and more happily than formerly as the result of the unnoted studies made by the family doctors

The *Tribune* writer probably has in mind that paragon of physicians which is also the ideal portrayed by the constitutions and codes of ethics of medical societies

## STATE MEDICINE

Dr S Parkes Cadman was asked the following question.

"Do you not think after a medical student has received his medical degree he should be controlled by the State government in order to abolish the exorbitant fees usually charged by physicians?"

He answered it in his Department of the *New York Herald-Tribune* of August 16, as follows

"I do not State controls should be avoided wherever possible State regulation has its uses when applied to injurious monopolies Such control has no legitimate function in any of the learned professions, and one taste of its quality is a convincing reminder of the wisdom of this position

"Socialized forms of medical and surgical service already exist in the numerous public dis-

pensaries, clinics and endowed or municipal hospitals, of which the plain people take full advantage. The remedy for exorbitant fees is in the courts, provided a personal appeal to the physician himself fails.

"The best traditions of his vocation are honorably sustained by the vast majority of its representatives. They are altruistic servants of the community, and this despite the fact that they are beset on all sides by quacks and charlatans.

Their custom of grading fees according to the patients' ability to pay brings the finest scientific skill within the reach of the poor and makes the rich help to bear the common burdens of disease and affliction. Leave the doctors alone. When they have exterminated fee splitting, their record will mount higher."

This is the answer which a physician would give, and is according to the ethics of the Medical Society of the State of New York.

## PROGRESSIVE POLYGAMY

Is there usually a medical aspect in divorces? Psychoanalysts say that sex enters into the majority of abnormal mental states, but that the conscious idea of sex is suppressed and appears in other forms such as love and dress display, or of applause, or notoriety.

Two questions arise regarding the relation of physicians to the prevention of divorce.

First, can the premonitory signs of impending separations be diagnosed?

Second, can a physician give effective treatment to a quarrelling man and wife?

The public discussion of the prevention of divorces has been carried on principally by sociologists and church leaders, and comparatively little is said regarding the medical phases of the problem. An editorial writer in the *New York Herald-Tribune* of July 26, says

"Dr Stetson of Trinity Church has given a damning name to the practice of serial marriages and divorces which has grown under legal and even social sanction. He calls it 'progressive polygamy,' which he thinks 'more menacing to society' than 'the legalized polygamy of the East,' which the Bishop of New York has been loud in condemning in Turkey, though legal

sanction for it has there been withdrawn. The legalized polygamy of the East has at least not left childhood without a home. That is more than can be said for serial rather than synchronous polygamy. When one in every six marriages is ended by divorce, and divorce means in most cases wreckage of the home, it is difficult to overestimate the menace to the oncoming generation."

The editorial quotes Dr Stetson's belief that laws are powerless to prevent divorces, but that "If the churches stood aggressively together in this view of their responsibility, they should be able to quicken such a sentiment in support of our traditional respect for the institution of marriage as would protect it even against the 'progressive polygamy' which certain states not only tolerate but encourage. They might even aid by refusing, as Dr Stetson suggests, to let their sanctuaries be used for the ostentatious and vulgar celebration of a sordid relationship which to all intents and purposes is pagan."

To this might well be added the advice to the incompatible man and wife to seek the counsel of a wise physician at the beginning of their marital troubles. Physicians settle more family quarrels than are generally known.

## PUBLIC OPINION

The editorial page of the *New York Herald-Tribune* of July 29 explains why the promoters of wild theories receive notoriety and acquire followers. The writer quotes Dr Nicholas Murray Butler as saying

"Don't listen to the big noises, listen to the silences. It is the opinion of the quiet, thoughtful persons throughout America which really counted but did not often get displayed on the front pages of the newspapers."

Commenting on this statement, the writer says

"If a politician makes a statement in a headline, or a propagandist asserts an argument in a pamphlet, it is almost beyond the powers of human nature for each reader not to suppose himself so superior to all the others that he alone

can understand the fallacy. It leaves the conviction in everybody's mind that everybody else must have been taken in by it, and so every one bows down in trembling before the big noise in the dread certainty that it must represent what all the others are thinking."

"Certain tabloid newspapers thrive upon abuse because the more they are abused the more do their subscribers read them in order to learn the depths to which all the other subscribers are sinking."

However, the time element must be taken into consideration. The "Big Noise" is potent news only while it is novel. It soon becomes stale and commonplace, and is forgotten save by the antiquarian who seeks the ghosts of the past in the yellow files of vaudeville newspapers.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers.

**THE HEALTH OF THE CHILD OF SCHOOL AGE.** By Various Authors With a foreword by Sir THOMAS OLIVER M.A., M.D. 12mo of 204 pages New York and London, Oxford University Press, 1927 Cloth, \$1.80 (Oxford Medical Publications)

**AN ILLUSTRATED GUIDE TO THE SLIT-LAMP** By T. HARRISON BUTLER, M.A., D.M. Quarto of 144 pages, illustrated New York and London, Oxford University Press, 1927 Cloth, \$9.00 (Oxford Medical Publications.)

**MALARIAL PSYCHOSES AND NEUROSES** With Chapters Medico-Legal, and on History Race Degeneration, Alcohol, and Surgery in Relation to Malaria By William K. Anderson, M.D. Quarto of 395 pages, illustrated. New York and London, Oxford University Press, 1927 Cloth, \$13.00 (Oxford Medical Publications)

**PRACTICAL OTOTOLOGY** By MORRIS LEVINE, M.D. Octavo of 387 pages, with 145 illustrations Philadelphia, Lea and Febiger, 1927 Cloth, \$5.50

**SURGICAL ANATOMY OF THE HUMAN BODY** By JOHN B. DEEVER, M.D. 2nd Edition. In 3 volumes, thoroughly revised and rearranged

Volume II Upper Extremities, Neck, Shoulders, Back, Lower Extremities Quarto of 854 pages, illustrated. Philadelphia, P. Blakiston's Son and Company 1926

Volume III Joints of the Lower Extremities, Chest, Thorax, Abdomen, Pelvis, Perineum. Quarto of 763 pages illustrated Philadelphia, P. Blakiston's Son and Company, 1927 Cloth, sold by subscription to the 3 volumes, at \$36.00

**LISTER, AS I KNEW HIM** By JOHN RUDD LEESON M.D. Octavo of 212 pages. New York, William Wood and Company, 1927 Cloth, \$3.50

**THE LIFE AND WORK OF SIR PATRICK MANSON** By PHILIP H. MANSON-BAHR, D.S.O., M.D., and A. ALCOCK, C.I.E., LL.D. Octavo of 273 pages New York, William Wood and Company, 1927 Cloth \$5.50

**TROPICAL SURGERY AND SURGICAL PATHOLOGY** By KARUNA K. CHATTERJI F.R.C.S.I. With a foreword by Sir R. HAVELOCK CHARLES Octavo of 244 pages illustrated New York, William Wood and Company 1927 Cloth, \$6.00

**TEXTBOOK ON DISEASES OF THE SKIN AND SYPHILIS** Designed for the Use of Students and Practitioners By ALBERT STRICKLER, M.D. Octavo of 689 pages illustrated. Philadelphia, F. A. Davis Company, 1927 Cloth, \$8.00

**RECENT ADVANCES IN HAEMATOLOGY** By A. PINEY M.D. Octavo of 276 pages illustrated Philadelphia P. Blakiston's Son and Company, 1927 Cloth \$3.50

**SEGREGATION AND AUTOGENY IN BACTERIA** A Contribution to Cellular Biology By F. H. STEWART M.A., D.Sc., M.D. Octavo of 104 pages illustrated London, Adlard and Son Ltd, 1927 Boards 7s 6d Net

**AN OUTLINE HISTORY OF OPHTHALMOLOGY** By THOMAS HALL SHASTID, A.M., M.D. Octavo of 34 pages Southbridge, Massachusetts, American Optical Company, 1927 Cloth, retail price \$1.25 Selling Agent George Wahr, Ann Arbor, Michigan.

**PULMONARY TUBERCULOSIS** By G. T. HEBERT, M.A., M.D. 12mo of 212 pages New York and London, Longmans, Green and Company, 1927 Cloth, \$3.00

**THE RELIGION CALLED BEHAVIORISM** By LOUIS BERMAN, M.D. 12mo of 153 pages, illustrated. New York, Boni and Liveright, 1927 Cloth, \$1.75

**HEART AND ATHLETICS** Clinical Researches Upon the Influence of Athletics Upon the Heart. By FELIX DEUTSCH, M.D., and EMIL KAUF M.D. English translation by LOUIS M. WARFIELD, A.B., M.D. 12mo of 187 pages St. Louis, The C. V. Mosby Company, 1927 Cloth \$2.50

**THE PSYCHOLOGY OF MENTAL DISORDERS** By ABRAHAM MYERSON, M.D. 12mo of 135 pages New York, The Macmillan Company, 1927 Cloth, \$1.40

**THE CAUSE AND CURE OF SPEECH DISORDERS** A Text Book for Students and Teachers on Stuttering, Stammering and Voice Conditions By JAMES SONNETT GREENE, M.D., and EMILIE J. WELLS, B.A. Octavo of 458 pages, illustrated. New York, The Macmillan Company, 1927 Cloth, \$4.50

**CITY HEALTH ADMINISTRATION** By CARL E. McCOMBS, M.D. Octavo of 524 pages New York, The Macmillan Company, 1927 Cloth, \$5.50

**HOW TO MAKE THE PERIODIC HEALTH EXAMINATION** A Manual of Procedure. By EUGENE LYMAN FISK, M.D. and J. RAMSER CRAWFORD, M.D. Foreword by Major General MERRITT W. IRELAND Octavo of 393 pages, illustrated New York, The Macmillan Company, 1927 Cloth, \$4.00

**CYSTOSCOPY** A Theoretical and Practical Handbook Containing Chapters on Separate Renal Function and Pyelography By JAS. B. MACALPINE, F.R.C.S. 12mo of 284 pages, illustrated. New York, William Wood and Company, 1927 Cloth, \$7.00

**LECTURES ON INTERNAL MEDICINE.** (Delivered in the United States, 1926) By KNUD FABER M.D. Octavo of 147 pages illustrated New York, Paul B. Hoeber, Inc., 1927 Cloth, \$3.00

**APPROACHING MOTHERHOOD** Questions and Answers of Maternity By GEORGE L. BRODHEAD, M.D. 3rd Edition 12mo of 193 pages New York, Paul B. Hoeber, Inc., 1927 Cloth, \$1.50

**HERNIA AND HERNIOPLASTY** By ERNEST M. COWELL, D.S.O., M.D. With an introduction by Sir ARTHUR KEITH F.R.C.S. Octavo of 128 pages illustrated. New York Paul B. Hoeber, Inc., 1927 Cloth, \$3.50

**PRACTICAL LECTURES ON THE SPECIALTIES OF MEDICINE AND SURGERY** Delivered under the Auspices of the Medical Society of the County of Kings, Brooklyn New York (Second Series, 1924-1926) Octavo of 590 pages illustrated, with 110 illustrations New York, Paul B. Hoeber, Inc., 1927 Cloth \$7.00

# BOOK REVIEWS

**LABORATORY OUTLINES IN BACTERIOLOGY AND IMMUNOLOGY** By JOHN F. NORTON, Ph.D., and I. S. FALK, Ph.D. Octavo of 114 pages. Chicago, Illinois, The University of Chicago Press, (1926) Cloth, \$2.00

This is a laboratory manual for instructors and students in a one year course in bacteriology and immunology. It carries the student through the preparation of culture media, microscopic examination of cultures, methods with typical pure cultures, action of disinfectants, study of groups of bacteria including anaerobes, examination of water and milk, vaccine preparation, immune reactions, Wassermann test, toxin-antitoxin reactions and anaphylaxis.

It is arranged in the form of two hour laboratory periods, the directions are concise and practical and the course is so designed that portions may be omitted if the instructor desires to make it shorter and more elementary.

E. B. SMITH

**THE MEANING OF DISEASE. An Inquiry in the Field of Medical Philosophy** By WILLIAM A. WHITE, A.M., M.D. 12mo of 220 pages. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$3.00

To the reader who enjoys a little philosophy now and then as a change in mental diet, we heartily recommend this little book. A chapter at a time with a cigar or pipe will prove both stimulating and interesting. Dr. White calls his study an "inquiry in the field of medical philosophy." He believes that too much time has been devoted to analytic studies in medicine and not enough to synthesis, to an attempt to put together the data of analytic science and formulate a theory of disease as such. This is the special province of philosophy. Only in the work-shop of the mind can one formulate a theory. To this task Dr. White brings one of the best mental work-shops in America, a mind rarely educated and endowed. To refute those who scoff at theories he quotes Whitehead. "It is no paradox to say that in our most theoretic moods we may be nearest to our most practical applications."

Dr. White regards the living body as an energy system in conformity with the latest scientific thought on the ultimate structure of matter. Mind and body are not separate entities, disease is an inadequacy of organ or mind or both. When one is affected, the other reacts also. Mental stresses have physical reactions and physical disease causes mental reaction. Symptoms may be grouped in pairs of opposites according to the law of action and reaction. If we could read symptoms correctly we could understand the patient's subconscious mind and find therapeutic indications. There is much more that is most interesting and suggestive. One catches brief glimpses of great possibilities when our capacity and knowledge have sufficiently increased.

E. B. SMITH

**THE NATURAL INCREASE OF MANKIND** By J. SHIRLEY SWEENEY, M.A., M.D. Octavo of 185 pages. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$4.00

This critical study of the growth of population thoroughly covers a complicated problem in a clear logical way. The relative values of vital indices or birth-death ratios with the effect of war and pestilence on their trends is analyzed by an ingenious statistical method. International agreement to control over population by a "League of Stationary Populations" is the author's solution. A philosophical introduction by Dr. William

H. Welch in which he calls attention to Malthus' disapproval of contraceptive measures adds much to the book.

C. A. G.

**THE SCIENTIFIC BASIS OF CHEMOTHERAPY** By IWAN I. OSTROMISLENSKY, Ph.D., M.D. 12mo of 142 pages. New York (The Author), 1926. Paper

This little volume of 137 pages is Part I of a series of several monographs in preparation and to be issued as completed. They represent the results of 12 years of research in chemotherapy in Russia and the United States. The author presents his "dualistic theory" of the mode of action of specific anti-bacterial drugs. He concludes that a chemotherapeutic agent, to be effective, must consist of a chemical toxic for bacteria plus a colloid which has a special affinity for bacteria. These absorb the colloid allowing the toxic fraction to act upon the bacteria. He presents experimental work with salvarsan and quinine which seem to support his theory. If true, it would seem to rationalize chemotherapy and open up wide fields for research. The author then describes pyridium, a relative of quinine, which he first synthesized. He cites experiments to prove its bactericidal power and safety for use in animals and humans either by mouth or local application. He does not recommend its use intravenously. He claims this drug has a specific effect on various cocci but little or none on bacilli and concludes with numerous case reports showing good results in pyogenic infections and acute and chronic gonococcus infections in both sexes.

E. B. SMITH

**PHYSIOLOGY AND BIOCHEMISTRY IN MODERN MEDICINE.** By J. J. R. MACLEOD, M.D., LL.D. Assisted by ROY G. PEARCE, A.C. REDFIELD, N. B. TAYLOR, and J. M. D. OLMSTED and by others. 5th Edition. Octavo of 1054 pages, with 291 illustrations, including 9 colored plates. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$11.00

A new edition of Macleod is always interesting and welcome and needs no reviewer's praise.

While medicine is progressing in every direction, the fields of physiology and biochemistry are forging ahead so rapidly, that it is barely possible for any book to keep abreast. This explains the frequency of new editions. Dr. Macleod and his co-workers are to be congratulated on their successful attempt to be up to date in these extremely important and fascinating subjects.

The sections on carbohydrate metabolism, respiration, and ductless glands have been rewritten and are just brim full of the latest developments along those lines.

Like the previous editions, this one is also characterized by a clear presentation, an interesting style and excellent typographical work.

BENJAMIN DAVIDSON

**THIS BUSINESS OF OPERATIONS** By JAMES RADLEY, Foreword by J. M. WITHROW, M.D. 16mo of 96 pages. Cincinnati, The Digest Publishing Company, 1927

This very small book of 96 pages with a foreword by J. M. Withrow, M.D., Chief of Staff of the Christ Hospital, Cincinnati, was written, apparently with the idea of being humorous. The idea is old and the whole story could be easily taken care of in five pages. A layman might find snatches of humor in it but from a professional standpoint it is a total loss.

**PRINCIPLES OF PHYSICAL CHEMISTRY FOR MEDICAL STUDENTS** By PHYLLIS M TOOKEY KERRIDGE, M.Sc. With Introduction by PROF A. V HILL, M.A., F.R.S. 12mo of 134 pages, illustrated. London and New York, Oxford University Press [1927] Cloth, \$1 75 (Oxford Medical Publications)

The author states, in a charmingly written preface, "The aim of this work is to give him (the student), briefly, some of the principles of physical chemistry which have been, up to the present, of great service for application to physiological and medical problems." There is an introduction by Prof A V Hill, in which he says, "Teaching, like physiology, is an experimental science. Some years ago, I was fortunate enough to persuade Mrs. Kerridge to experiment in the teaching of physical chemistry to medical students. She has been as successful in this as in her other researches. The ordinary text-book of physical chemistry is too large, too abstract, to be suited to the needs of a student of medicine. There is no book which exactly meets the need."

While this little book may not exactly meet that need, it fills a gap. It furnishes a good birdseye view of many important physico-chemical principles. They are described in terse, succinct and accurate statements. A few errors have been noted, as on page 31, where the statement occurs, "Henry's Law states that the solubility of a gas in a liquid varies directly as the temperature," and on page 41, where the definition of equivalent conductivity in general is confused with that for the equivalent conductivity at infinite dilution.

From this little book, the student can get an appreciation of the method and content of physical chemistry. It should prove useful as an introduction to the subject.

M. J SHEAR

**DENTAL MATERIA MEDICA AND THERAPEUTICS** A Text-book for Students and Practitioners By HERMANN PRINZ, A.M., DDS, M.D. 6th Edition, enlarged and revised. Octavo of 632 pages, illustrated. St. Louis, The C. V Mosby Company, 1926 Cloth \$6 00

The sixth edition of this very well-known textbook of dental materia medica and therapeutics, maintains the high standard of the previous editions.

It is a comprehensive manual that covers everything of importance in the field of dental medicine. This is accomplished, not only by written word and numerous instructive illustrations, but also by a very well-planned division of the book into chapters, titles and subtitles.

In addition, it has a properly classified index of drugs according to their uses, which will be of great help to the busy practitioner and makes this volume a handy reference book.

This materia medica will continue to be regarded as the standard textbook for the dental student and practitioner, as it has been for the last fifteen years.

OSCAR RODIN

**A TEXTBOOK OF EXODONTIA. Exodontia, Oral Surgery, and Anesthesia.** By LEO WINTER, DDS. Octavo of 364 pages, with 329 illustrations. St. Louis, The C V Mosby Company, 1927 Cloth, \$7 50

This is a good sized book, not only on Exodontia but also on Anaesthesia and Oral Surgery. It is very profusely and clearly illustrated with diagrams, charts, and plates.

The subject of Anaesthesia in relation to Exodontia and Oral Surgery, which certainly is very important, takes up about a third of the book and includes not only one chapter on General Anaesthesia written by J T Gwathmey, but many chapters on local anaesthesia prior to extraction. This phase of the subject is quite lengthy but very readable and very practical, so that every detail is mentioned and its importance noted. Of special interest is the technique of injection, the accidents and infections resulting therefrom and the treatment or remedies for them.

Exodontia—the extraction of teeth—takes up the re-

maining pages and this in a very thorough and painstaking manner, not only in ordinary temporary and permanent teeth, but a good deal of space is given over to the problem of impacted teeth. This problem in Oral Surgery, which now seems to be occupying the attention of the dental profession, is discussed very adequately. Each different anatomical impaction is taken up separately and the operations described step by step. It is a field of Oral Surgery wherein Leo Winter has shown most experience and original work.

This volume, without doubt, is one of the best on the subject and one that can be highly recommended not only to the student and general dental practitioner, but to the Exodontist as well.

OSCAR RODIN

**CLINICAL NEUROLOGY FOR PRACTITIONERS OF MEDICINE AND MEDICAL STUDENTS** Largely Based Upon the Book by PROF DR HANS CURSCHMANN (A Free Translation with Changes and Additions.) By EDWARD A. STRECKER, MD and MILTON K. MEYERS, MD. Octavo of 410 pages. Philadelphia, P Blakiston's Son and Company, [1927] Cloth, \$3 50

This book of clinical neurology has been written for the general practitioner rather than for the medical student. A short incomplete sketch of some of the neurological conditions are found but in order to save time for the busy practitioner, the authors have inserted a half page resume of the points of interest at the beginning of the various subjects. The material in this book has been boiled down to such a consistency that it can easily be devoured and the entire subject of Neurology can be covered in one evening.

O C P

**APPLIED PHYSIOLOGY** By SAMSON WRIGHT, MD With introduction by SWALE VINCENT MD. Octavo of 418 pages, illustrated. London and New York, Oxford University Press, [1926] Cloth, \$4 50 (Oxford Medical Publications)

This book is not, nor does its author claim it to be a scientific treatise on human physiology, but it is, as its author evidently intended it should be, a manual in which are presented, clearly concisely and systematically, those portions of such a treatise with which the up and coming practitioner of medicine should be familiar, because they are essential for intelligent interpretation of clinical findings. The physiological are brought into rational correlation with a considerable amount of morphological, pathological and clinical matters of fact and theory, the diagnostic value of the whole made apparent and the intimacy of interrelationship of human physiology, pathology and clinical medicine thus clearly displayed. Attention is directed, especially to the great value of physiologic evidence derived from careful analysis of certain disease states and further bedside study of the problems involved is encouraged because by means of such evidence human physiology is directly advanced.

The avidity with which alert practitioners have grasped and clinically applied certain recent advancements in animal physiology is outstanding evidence of a general desire for such a manual. Though not a large book it is gratifyingly comprehensive, unusually explicit and replete with current explanations of syndromes which confront, and are likely to confuse insufficiently informed clinicians, in this respect supplementing, rather than replacing standard treatises on physiology. Therefore it is frankly recommended as a valuable handbook to students, hospital internes and practitioners or medicine, alike.

The author's discriminative care in the selection of material proper to such a manual and his evident skill in the general arrangement and specific combination of that material are highly commendable, and he is to be congratulated for having accomplished the difficult task of furnishing our medical schools and profession with a really useful manual of applied physiology.

# OUR NEIGHBORS

## PELLAGRA

Pellagra is an important disease in Oklahoma, and has been increasing in recent years. For the year 1926, 543 cases were reported with 242 deaths. Dr. Joseph Goldberger, of the U. S. Public Health Service, estimates that there are at least 5,000 cases of pellagra in Oklahoma.

These facts are given in two papers read before the Oklahoma State Medical Society in May and published in the June Journal of the Oklahoma State Medical Association.

Dr. F. M. Adams discussed the cause of the disease and said that the three causes usually given were first, infection, second, a deficiency in the proteins of food, and third, the lack of some constituent analogous to that in scurvy.

Dr. G. E. Harris described some outbreaks which he saw.

The symptoms may be grouped in three classes:

1. A dermatitis, beginning on the parts exposed to the sun.

2. Gastro-intestinal disturbances, especially pain and indigestion.

3. Neurological conditions, depression, insomnia, unfounded fears and dementia.

A diagnosis is made from the skin lesions. While these are usually early signs, the mental symptoms may become fully developed before the dermatitis.

The skin lesions are described as follows:

**"SYMPTOMS.** There is a dermatitis of the dorsal surfaces of the hand gradually extending up the extensor surfaces of the arms and many times well above the elbows, and frequently a dermatitis of the neck, upper portion of the chest, the malar prominences, forehead and often times the dorsum of the feet. There is a reddening and ulceration of the buccal and lingual mucous membrane and in fact a disturbance of the entire gastro-intestinal tract with diarrhea."

The treatment is principally dietary, and is described as follows:

"The diet should consist of highly nutritious foods. Meats, as a rule, agree with pellagrins and should form an important part in the diet, especially, beef steaks and beef extracts. Milk and eggs should also be given at least twice a day. Beans, garden peas, black-eyed peas, spinach and, in fact, most garden vegetables. Fresh tomatoes in season should be given often and when the fresh tomatoes are not available the juice of canned tomatoes may be substituted.

"With this balanced diet the patient should be given two ounces of dry brewer's yeast each day. This may be mixed in the milk or be given with other foods and is usually well borne by the patients. We have been treating all of our patients with yeast for the past year, and the results have been very gratifying. I think it is a very advanced step in the treatment of this disease."

The results are described as follows:

"We receive in the State institutions the more advanced cases, and our results in the most serious cases have been good. In a very few days these patients begin to improve mentally and physically and in a few months are able to return to their home. They are advised as to the cause of the disease and a diet and treatment is prepared for them before they leave the hospital, but most of them are from the very poorest homes and do not have the funds to provide the balanced diet and already they are returning to the institution, from last year, with a new outbreak of pellagra. This is one of the serious questions, not only for the patient discharged from our hospitals but for the patient treated by the general practitioner, as most of the patients do not have the means to purchase the proper food and carry out the treatment as outlined."

## WHY JOIN THE WOMEN'S AUXILIARY?

The *Virginia Medical Monthly* for July, 1927, tells why the wives of physicians should join the Women's Auxiliary. It is by Mrs. F. P. Gengenbach, Retiring President, Women's Auxiliary to the American Medical Association.—EDITOR'S NOTE

"The question has been asked so often—'What is this Auxiliary?' What is it for?' Then follows the remark, 'I already

belong to so many societies I do not wish to join another'.

"The women who are already members have caught the vision and see a great future for the Auxiliary, but to those who are not yet members, and we want you all to be with us, I would like to say, 'I belong to the Auxiliary—Because—'

It is not the intention of the managers of the State Journals of Medicine that the Journals shall be money-makers, although that would be desirable. Practically all journals in the business and literary worlds would lose money if they charged no subscriptions. Medical Journals too, must meet deficits out of the annual dues of the societies.

# The Gold Medal Cod Liver Oil

*The Sesquicentennial Gold Medal awarded at Philadelphia as a recognition of the high quality of*

## PATCH'S FLAVORED COD LIVER OIL

At the Sesquicentennial Exposition held in Philadelphia last year, the E L Patch Co was awarded the gold medal for "excellence of product."

This award is only one of the various forms of recognition which our product has received.

The recognition given to our product by the medical profession, after five years of clinical experience, constantly reminds us of our great responsibilities.

Here are a few reasons why Patch's Flavored Cod Liver Oil is dependable.

It is made in our own plants along the North Atlantic Coast, from FRESH LIVERS.

Every lot is biologically assayed. The vitamin potency is guaranteed.

The dose is small,—a half teaspoonful for children or a teaspoonful for adults three times a day.

It is pleasantly flavored. Your patient will appreciate this feature.

Let us send you a trial bottle of this "Gold Medal Cod Liver Oil."

Taste it! You'll be surprised.

"I believe that my husband's profession is one of the finest in the world, almost the greatest work a man can do.

"His profession not only uses all of its knowledge and power to cure disease, but goes farther, and does what no other profession will do, that is work against its own interests in order to help humanity. By that I mean preventive medicine.

"I believe that my husband is one of the finest men in his profession and I wish to back him in this work to which he gives his life.

"I also belong to many other organizations, but I believe that first I should center my interests and energies on the work which is nearest my home and my heart because my position as a doctor's wife surrounds me with opportunities for investigation of the health question and an understanding of that problem which perhaps others may not have.

"I have discovered that through the Auxiliary I may become the friend of any doctor's wife, not only of my state but of my country, and thus enrich my life.

"And, finally, I believe in and am a member of the Women's Auxiliary to the A M A because I accept the following statement that each succeeding generation of the race is the beneficiary of the care bestowed by the womanhood of the generation before it."

"And I wish to carry on.

"If you believe these statements to be true, will you not lend your strength to this movement by joining your state and county Auxiliaries and by attending their meetings?"

## THE TEXAS STATE JOURNAL OF MEDICINE

The sixty-first annual session of the State Medical Association of Texas was held in El Paso, April 26-28, 1927, and is reported in the June issue of the *Texas State Journal of Medicine*. An interesting feature of the meeting was the report on the finances of the *Texas State Journal of Medicine*, which goes to each of the 3,600 members of the State Association. The *Journal* costs the Association about \$7,000 more than its receipts, but the deficiency is made up by an appropriation of \$250 out of the \$10 annual dues per member as a subscription charge. The report is as follows:

Please mention the JOURNAL when writing to advertisers

shows the changing of the eosinophils to basophils, but the percentage of these stippled cells will be high. Eosinophile counts up to 42 and 47 per cent were obtained in the cases here related.

"Specimens of any pork sausage or other raw pork products from which the patient has eaten should be sent to a laboratory for examination. A piece of deltoid muscle removed from one of the Lancaster patients was found to contain trichinae."

"In treatment, recent suggestions have indicated the value of neoarsphenamin, or a similar drug, as a parasiticide, but such treatment should probably be administered as easily as possible and before the stage of encysting has commenced."

### PHYSICIANS ON THE MAYFLOWER

Dr Samuel Fuller was the physician to the Plymouth Colony until his death in 1633, from an infectious fever. He was a wise man, and was skilled in the practice of medicine. He was successful in treating Massasoit, the Indian chief, who seemed to be dying from an abscess of the mouth. But it has only recently been discovered that a doctor, named Giles Heale, was among the crew of the Mayflower. This fact is discussed editorially in the July issue of the Illinois Medical Journal, which says:

"The discoverer of the great unknown is Charles Edward Banks, a member of the Massachusetts Historical Society, and it is only a few days since he published the story. He devoted 1922-26 to delving in the national archives of England, France and Holland and to special efforts to identify Pilgrims unknown. A copy of the muncupative will of William Mullins, who died on March 3, 1621, had been found in 1886 by H F Waters, and in 1926 Mr Banks discovered the original. Here were the veritable signatures, as witnesses, penned by Governor John Carver, Captain Christopher Jones of the Mayflower (whose Christian name had been unknown) and Dr Giles Heale. This was the first will ever made in New England.

"The medical man had been admitted to the London guild of surgeons on August 3, 1619, exactly a year before the Pilgrims left Holland, and it was the vogue for surgeons to serve on passenger ships voyaging 'beyond seas.' He came to America voluntarily, and not improbably aimed at commencing his career in a new country. The pioneer's fiber would, however, seem to have been absent from his makeup, for he left Plymouth in April, 1621, and practiced medicine at London until his death on or about February 3, in 1652 or 1653."

## TRICHINOSIS

The Atlantic Medical Journal for June contains an editorial on two recent outbreaks of trichinosis in Pennsylvania, caused by eating pork that had been imperfectly cooked. It quotes from a bulletin of the State Department of Health that salting, pickling, or smoking pork, when it is done thoroughly, will kill the trichinae, but thorough cooking is advised for all pork products. The subject is of interest to physicians of New York State, for cases of trichinosis frequently come to the attention of the State Department of Health. Concerning the cases and their symptoms, the editorial says:

"Originally these cases were reported to the State Health Department as typhoid fever. Department investigations, however, together with laboratory tests, indicated trichinosis."

"The incubation period of trichinosis is short, mostly five or six days in the cases here described."

"Trichinosis develops suddenly with abdominal pain, vomiting, diarrhea, headache, or chills as the first evidence of illness. The two principal symptoms of the disease are diarrhea and muscular pains. The diarrhea rapidly becomes profuse, the stools are frequently black and very offensive, later becoming slightly blood-streaked or mucous. The combination known as typhoid symptoms are commonly found in trichinosis."

"The muscle symptoms of trichinosis are characteristic, and are apt to begin from the second to the fourth day. The pain may resemble a generalized myalgia, or may be localized. The muscular symptoms are caused by the deposition of the trichinae in the muscles, and their character apparently depicts the stage of development of the parasite."

"The diagnosis of trichinosis is made substantially after laboratory confirmation. The disease is chiefly confused with typhoid fever, but may also be diagnosed as rheumatism or intestinal grip. The distinguishing points which differentiate trichinosis from typhoid are the sudden onset, profuse diarrhea, and muscular pains, and the presence of general typhoid symptoms. Particularly should trichinosis be considered when a typhoid suspect is found lying with arms flexed and complaining of pain upon extension. With this combination of symptoms, inquiry should be made in regard to the recent eating of pork, chiefly raw pork or smoked sausage. If such a history is obtained, and even in its absence, a blood smear should be made for a differential count to determine the presence of eosinophilia. There is a marked rise in the eosinophilic count, which persists after the cessation of symptoms, although late in the attack the blood picture

shows the changing of the eosinophils to basophils, but the percentage of these stippled cells will be high. Eosinophile counts up to 42 and 47 per cent were obtained in the cases here related.

"Specimens of any pork sausage or other raw pork products from which the patient has eaten should be sent to a laboratory for examination. A piece of deltoid muscle removed from one of the Lancaster patients was found to contain trichinae."

"In treatment, recent suggestions have indicated the value of neoarsphenamin, or a similar drug, as a parasiticide, but such treatment should probably be administered as early as possible and before the stage of encysting has commenced."

## BACTERIA CAUSING STONE DECAY

That living bacteria can cause disease and degeneration in building stone is the assertion made in the London letter of the June 11th issue of the *Journal of the American Medical Association* from which the following quotations are taken—EDITORIAL NOTE

"The report of the stone preservation committee has been submitted to the building research board of the department of scientific and industrial research. Broadly speaking, this study has two aspects (a) chemical, physical and geological, and (b), biologic

"It appears that the microstructure of building stones is of primary importance and that the distribution of the pores in the stone is a preponderating factor in determining the rate of attack. It was realized from the first that the investigation of the biologic activity in such a specialized medium as was presented by stone would call for new methods of bacteriologic technic. A good beginning had been made in this direction and it was now possible to determine the actual bacterial content of different kinds of stone and of the same kind of

stone under different degrees of weathering. It had been established that stone, apparently sound, might contain bacteria in considerable numbers, that, in fact, microorganisms are present in the stone quarry to a depth of two feet below the quarry face. Stone floras were limited to a small number of species, so far only twelve had been observed. These have been isolated and maintained in pure culture and are now under investigation, culturally and physiologically, with a view to the appraisal of their importance in the processes of stone decay. It is not yet possible to say whether bacteria play an important part in the processes of stone decay. On isolating the bacteria from a certain specimen of weathered stone, the colonies which developed on the plate were all of one kind. This fact, sufficiently significant in itself, was rendered still more so when, on investigation of the characteristics of this species, it was found capable of making luxuriant growth on an artificial medium so poor in organic food material that the life of other bacteria was barely supported."

## OPERATING IN PRE-ANTI-SEPTIC DAYS

Physicians of the present day can scarcely realize the conditions under which surgical operations were done in the years as late as the early "eighties." There was much of the spectacular and the dramatic (which was a part of the capital of many great surgeons) in the operating room. Skill was shown by rapidity of operating in afternoon dress that was proper for a parlor reception. Such a scene is described by Dr R J Reed in the *West Virginia Medical Journal* of June—EDITORIAL NOTE.

"In every medical center there is usually found one striking personality possessing certain outstanding, fascinating characteristics by which the crowd is drawn. A clinical professor of surgery was the particular star of old Bellevue, Professor James Woods, familiarly and affectionately known as 'Jimmie Woods'. He performed every Saturday afternoon in the large amphitheatre in the great dome of the hospital, and it was always filled. As he entered from a wing in the rear, to the operating area amid great applause, he was followed by numerous satellites, an actual cavalcade, the chief of which was a Mr Ford, mechanician extraordinary to the House of Tieman. It was Mr Ford's prerogative to preside over the instruments and make sure that Jimmie was provided with perfect tools. These instruments were already in place on side tables when the performers entered. They rested in beautiful rosewood cases lined in velvet, until Jimmie should give the signal, when Mr Ford in street attire and with unkempt hands would speedily produce the shining blades. Jimmie himself was always attired in full afternoon dress, which in that day was the Prince Albert coat with a skirt unusually long and very flowing. A red rose invariably decorated the lapel of his coat and a white bow tie completed his operating outfit. When the patient was

brought into the amphitheatre already etherized and the Esmark in place, the sign given by Jimmie for beginning proceedings was the turning back of the sleeves of his Prince Albert. His favorite operation was amputation of the thigh and it was a dull Saturday if he did not have at least one victim. The moment the cuffs of the sleeves went back, the long steel blade came forth from the velvet lined box and the operation was on. One swift circular sweep and the skin flap was completed, the great knife going on, leaving the hand of the operator and striking the floor beyond with a bang—no time to pass an instrument to an assistant. This touch of the dramatic always gave a thrill to the students' spines, which was most satisfying and enduring. The flap was quickly dissected back, the muscles severed, the bone sawed through, and the act was over in less than two minutes. There was no preparation of the field for operation. There was no suggestion of any sterilization in gowns or towels or instruments or in the attire of assistants. The wound was left open and packed with oakum saturated with Balsam of Peru. This was a specimen of the surgery of Bellevue Hospital in the year '84."

"In West Penn Hospital, Pittsburgh, about this same time, there was a staff of eminent surgeons but they had not as yet experienced a true vision of aseptic surgery. As a result the internes spent entire mornings daily, going through the wards, which were always filled with traumatic surgical cases, armed with large brass syringes and supplied with carbolic solution—the Lister Treatment, if you please. A morning routine was to go from bed to bed, irrigating suppurating stumps, and infected wounds of every description. The same syringe was used from patient to patient without any attempt at disinfection. It was in the winter of '85 before any serious attempt was made to introduce true Listerian antiseptics."

## THE CANCER EXHIBIT OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

By FRANK OVERTON, M.D., PATCHOGUE, N Y

**A** CANCER Demonstration and Exhibit was held by the Medical Society of the State of New York in Niagara Falls on Thursday, May 12, 1927, the last day of the Annual Meeting of the State Medical Society. This Exhibit followed the precedent which was set by the Society in the preceding two years, to have an all-day exhibit devoted to some broad medical topic. That in 1925 in Syracuse was on Tuberculosis, and that in 1926 in New York was on Syphilis, and was the most comprehensive exhibit that had ever been got together on that subject. An account of the exhibit was published in this JOURNAL for June 15, 1926, a whole number being given principally to the subject.

The Demonstration of each year was under the auspices of the Committee on Scientific Work, of the State Society, that of 1927 on Cancer being in the immediate charge of Dr. Burton

T. Simpson, Director of the State Institute for the Study of Malignant Disease, in Buffalo. It was held in the Ball Room and an adjoining parlor of the Hotel Niagara, the headquarters of the State Society. It consisted of exhibits of specimens, educational material, and the presentation of papers designed to instruct general practitioners of medicine in the fundamental principles of anti-cancer work. But in order to understand the Exhibit and Demonstration, one should have in mind a general picture of cancer and the lines along which research has been conducted. It has therefore seemed best to prepare a description of the Cancer Demonstration in three parts:

1. An outline of the cancer problem
2. A description of the State Institute for the Study of Malignant Disease
3. An account of the Exhibit itself

### THE CANCER PROBLEM

**What Cancer Is.** The word *Cancer* is a lay term for an abnormal growth of new tissue of a malignant nature, that is, extending indefinitely until it causes the death of the person or animal on which it grows. The new growth is derived from the natural tissues of the body, and consists of the same kinds of cells as those of normal tissue, but they differ from the normal chiefly in the manner in which they grow. When normal tissues are wounded, they heal themselves by the growth of new cells which spring from healthy ones surrounding the wound. But the various groups of cells of the body differ widely in their ability to multiply and grow. Those of epithelium and connective tissue grow with great readiness and rapidity, while those of muscles and nerves grow very slowly or not at all. It is the epithelial and the connective tissue cells that multiply and become cancers, those of epithelium producing carcinomas, and those of connective tissue becoming sarcomas. But normal tissues, especially blood vessels and ordinary connective tissue, also multiply and grow with the cancerous cells.

In a general way it may be said that the degree of malignancy of a cancer may be estimated by the development of the cancer cells toward the nature state,—that is, the more immature the cells are, the more malignant is the new growth.

The scientific recognition of malignant tumors is made by their examination microscopically. This recognition may often be easy, or it may require all the skill of a trained specialist of long experience. This skill is especially required when a tissue, such as the edge of a gastric ulcer, begins to take on a malignant character.

Malignancy depends on two factors:

1. The growing cells
2. The soil in which they grow, that is, the whole body of the patient

It is accepted that cancer does not spring from a perfectly healthy area. It is likely to grow on a spot that is irritated or injured. In producing cancers experimentally, the irritation must be long continued. The first experiments to produce cancer in mice and rabbits failed because the irritation was carried on for only a short time.

Some animals will not produce cancers, even after long-continued irritation. The response of

the body to an irritation may be compared with that of a horse to an unusual irritation. One of a racing breed will run away at the touch of a whip, while a draught horse remains calm.

The response to irritation may also be illustrated by three brothers. The first one inherits stable cells. He smokes to excess, but the cells of his lip or tongue do not respond to the irritation, and his mouth remains normal.

The second brother inherits unstable cells, but he does not smoke or do other things to irritate his tongue, and his mouth, too, remains normal.

The third brother inherits unstable cells. He smokes and develops cancer of his tongue.

**Signs of Cancer** What signs are suggestive of cancer? This question may be answered by a consideration of the organs in which cancers develop the most frequently.

The stomach is the most frequent site of cancer. It affects both sexes equally, for both men and women have stomachs and subject them equally to use and abuse. Ten per cent of recognized gastric ulcers develop into cancers.

A stomach cancer develops insidiously, and when it is recognized it is usually too far advanced for removal. It usually produces signs of indigestion, that common American disease. Suggestive signs are, 1, X-ray disclosures, 2, occult blood in the stomach contents, and 3, absence of hydrochloric acid in the gastric juice.

The practical point for a family physician is to have cancer ever in mind whenever he treats a case of indigestion. He may examine and treat dozens and hundreds of cases of indigestion without running across one of cancer, but it is the recognition of the unusual that marks the skilled doctor.

The breast is the second most frequent site of cancer. The male breast seldom becomes cancerous, for it contains only rudimentary tubules, and seldom has secreting glands, which are the parts from which cancer springs.

Much of the experimental work on cancer has been done on cancer developing spontaneously in the breasts of white mice. The Institute has a strain of mice in which half of the females develop cancers of their breasts. When the experimental work was first undertaken some twenty-five years ago, mice with a tendency to breast cancer were difficult to obtain, but the inbreeding of cancerous mice has developed a strain in which many of the females develop cancers. These mice are the subjects of much of the experimental work on cancer.

Irritation of the breasts of the mice hastens the development of metastases from the original cancer. Massaging the breasts will cause a mouse cancer to metastasize three months instead of the usual average of five. This point may be applied to women. Frequently examining and feeling a lump in the breast is an effective

means of causing it to spread to other organs.

The incidence of breast cancer in mice is much increased by the removal of the young as soon as they are born. It may be that the failure of American women to nurse their children is a factor in the prevalence of cancer. It is a curious fact that no one has ever reported a cancer in the udder of a cow.

Cancer frequently effects the uterus, especially the cervix, which is peculiarly subject to irritation and chronic inflammation.

Cancer of the intestine is frequent at each end of the large intestine, the caecum and the rectum, both of which are subject to irritation. Cancer is rare elsewhere in the intestine.

These examples illustrate the important part that irritation has in the causing of cancer to develop. A practical point for every physician is to have consciously in his own mind the possibility of cancer when he is confronted with a tumor, or an old ulcer, or any chronic inflammation or irritation.

**Malignancy** A characteristic of malignancy is that secondary cancers develop in parts of the body remote from its first site, particles of the original being carried by the blood or lymph. This transportation of the causative agent of cancer from one part of the body to another suggests the possibility of transplanting a cancer from one animal to another. Many forms of cancer may be transplanted from one mouse to another, and the tumors which are produced may grow to a large size and eventually produce death. But there is always this peculiarity of transplanted tumor, it remains merely a graft and does not cause the body of the host to be cancerous. However, there is one form of cancer which may be transferred by inoculation and which causes the inoculated animal to become cancerous. What is known as the "Chicken Sarcoma" of Rous will produce a real sarcoma when it is inoculated into a chicken. This tumor originated from a single specimen of Plymouth Rock fowl that was brought to the Rockefeller Institute, and no other specimen has been discovered. Cultures from this specimen failed to grow at first until they were transferred to Plymouth Rock fowls from the same stock as the first case, but transplants now grow in most varieties of fowl.

Experiments with the chicken sarcoma of Rous have been the bases for alleged reports of the discovery of a living organism that produces cancer, but the State Institute has shown that extracts from a placenta or embryo may be used for the tumor extract in one stage of the experiment.

**Curability of Cancer** Is cancer curable? The answer to this question is similar to that regarding what was called "inflammation of the peritoneum" a generation ago, but what we now know to have been appendicitis. Most cases of

inflammation of the peritoneum were curable by the removal of the appendix. This fact is now so well known that physicians advise the operation and people accept it without question. But after the appendix has ruptured and extensive peritonitis has set in, inflammation of the peritoneum is as incurable as ever. The removal of the appendix is the only recognized cure for appendicitis.

The removal of the cancerous growth is the only recognized cure for cancer. Surgery is the most efficient method of their removal. But the growths will recur if metastases are left. The prevention of a recurrence depends on an early recognition of the tumor and an operation before metastases have formed.

Most people and some doctors do not consent to operations unless the diagnosis of cancer is positive. A diagnosis in the early stage of cancer is possible only by means of a microscopic examination. It has been the custom to excise a bit of new growth, and send it to a laboratory for examination and report. This procedure, called biopsy, has been condemned as leading to fatal delays and as opening up the channels for carrying metastases through the body. Biopsy performed with great care is done regularly at the State Institution in order to make certain the diagnosis of every case. If a biopsy is not done and a patient consents to an operation, an immediate examination of the tumor or specimen is done by a modified frozen section method in which a specimen of the tumor is boiled in formalin for one minute, and is then frozen, sectioned, stained, and examined, the whole procedure taking less than ten minutes if it is done by an expert. The operation is then continued according to the indications of the examination.

Next to surgery, radiation offers the best means of curing cancer. The theory of its action is that it will destroy the cancer cells while leaving the normal cells unharmed. It acts with considerable certainty when the cancer cells are reached with the full force of the radiant waves.

Radiant energy is derived from either the X-ray or radium. The agent in both is the same and consists of the so-called gamma rays. While radium is breaking down, it gives off alpha rays which are particles of positive electricity, beta rays, which are particles of negative electricity, and gamma rays, which are not material particles but are vibrations of short wave lengths like those of the X-ray.

Gamma rays are given off from an ordinary X-ray tube in an amount thousands of times greater than those from the larger capsules of radium used in treatments, but since the effect of the rays varies inversely as the square of the distance of their source, a small amount of radium in contact with the flesh is as powerful as a large amount of X-ray from a tube a foot or more from the flesh.

Radiation is a powerful agent whose effects are known as accurately as those of strychnine or arsenic, and whose dosage must be adjusted to the effects that are desired. Their application by an amateur is as dangerous and ineffective as the administration of strychnine by a layman.

The intelligent treatment of all recognizable cases of cancer by surgery or radiation would cut the present death rate in half. It would not reach one hundred per cent of cure, because many forms of cancer are not recognizable in their early stages by present methods of diagnosis.

It is unfortunate that incipient cancer does not give pain or produce alarming symptoms of illness. If cancer were as painful as toothache, or appendicitis, every person would demand relief in its early stage, and would demand an early operation for its removal.

**The Cause of Cancer** The cause of cancer still remains an alluring mystery, whose solution is often prematurely announced. The ordinary principles on which pathology is founded do not apply to cancers. A cancer is not a manifestation of inflammation, or infection, or allergy, or heredity. Yet cancer is curable in the same sense that tuberculosis or "inflammation of the peritoneum" is curable.

The curability of cancer, like that of tuberculosis, depends on two principal factors:

- 1 Early recognition and treatment
- 2 Accessibility

It is fortunate that the parts of the body on which the majority of cancers are located are accessible to sight or touch and give signs and symptoms early in the disease while it is in a curable state.

The immediate problem in cancer is the education of both physicians and the people so that they will take advantage of the means of cure which are already available.

#### THE STATE INSTITUTE FOR THE STUDY OF MALIGNANT DISEASE

The Legislature of New York State established the Institute for the Study of Malignant Disease in 1898 by the appropriation of \$10,000 upon the advice of Dr. Roswell Park of Buffalo. The medical profession expected that the original appropriation, generous for its time, would

enable research workers to discover a specific cause and cure of cancer within a year or two. Although this immediate object has not yet been attained, the Institute—the first of its kind in the world, has been the testing station where every conceivable clew concerning cancer has

the body to an irritation may be compared with that of a horse to an unusual irritation. One of a racing breed will run away at the touch of a whip, while a draught horse remains calm.

The response to irritation may also be illustrated by three brothers. The first one inherits stable cells. He smokes to excess, but the cells of his lip or tongue do not respond to the irritation, and his mouth remains normal.

The second brother inherits unstable cells, but he does not smoke or do other things to irritate his tongue, and his mouth, too, remains normal.

The third brother inherits unstable cells. He smokes and develops cancer of his tongue.

**Signs of Cancer** What signs are suggestive of cancer? This question may be answered by a consideration of the organs in which cancers develop the most frequently.

The stomach is the most frequent site of cancer. It affects both sexes equally, for both men and women have stomachs and subject them equally to use and abuse. Ten per cent of recognized gastric ulcers develop into cancers.

A stomach cancer develops insidiously, and when it is recognized it is usually too far advanced for removal. It usually produces signs of indigestion, that common American disease. Suggestive signs are, 1, X-ray disclosures, 2, occult blood in the stomach contents, and 3, absence of hydrochloric acid in the gastric juice.

The practical point for a family physician is to have cancer ever in mind whenever he treats a case of indigestion. He may examine and treat dozens and hundreds of cases of indigestion without running across one of cancer, but it is the recognition of the unusual that marks the skilled doctor.

The breast is the second most frequent site of cancer. The male breast seldom becomes cancerous, for it contains only rudimentary tubules, and seldom has secreting glands, which are the parts from which cancer springs.

Much of the experimental work on cancer has been done on cancer developing spontaneously in the breasts of white mice. The Institute has a strain of mice in which half of the females develop cancers of their breasts. When the experimental work was first undertaken some twenty-five years ago, mice with a tendency to breast cancer were difficult to obtain, but the inbreeding of cancerous mice has developed a strain in which many of the females develop cancers. These mice are the subjects of much of the experimental work on cancer.

Irritation of the breasts of the mice hastens the development of metastases from the original cancer. Massaging the breasts will cause a mouse cancer to metastasize three months instead of the usual average of five. This point may be applied to women. Frequently examining and feeling a lump in the breast is an effective

means of causing it to spread to other organs.

The incidence of breast cancer in mice is much increased by the removal of the young as soon as they are born. It may be that the failure of American women to nurse their children is a factor in the prevalence of cancer. It is a curious fact that no one has ever reported a cancer in the udder of a cow.

Cancer frequently effects the uterus, especially the cervix, which is peculiarly subject to irritation and chronic inflammation.

Cancer of the intestine is frequent at each end of the large intestine, the caecum and the rectum, both of which are subject to irritation. Cancer is rare elsewhere in the intestine.

These examples illustrate the important part that irritation has in the causing of cancer to develop. A practical point for every physician is to have consciously in his own mind the possibility of cancer when he is confronted with a tumor, or an old ulcer, or any chronic inflammation or irritation.

**Malignancy** A characteristic of malignancy is that secondary cancers develop in parts of the body remote from its first site, particles of the original being carried by the blood or lymph. This transportation of the causative agent of cancer from one part of the body to another suggests the possibility of transplanting a cancer from one animal to another. Many forms of cancer may be transplanted from one mouse to another, and the tumors which are produced may grow to a large size and eventually produce death. But there is always this peculiarity of transplanted tumor, it remains merely a graft and does not cause the body of the host to be cancerous. However, there is one form of cancer which may be transferred by inoculation and which causes the inoculated animal to become cancerous. What is known as the "Chicken Sarcoma" of Rous will produce a real sarcoma when it is inoculated into a chicken. This tumor originated from a single specimen of Plymouth Rock fowl that was brought to the Rockefeller Institute, and no other specimen has been discovered. Cultures from this specimen failed to grow at first until they were transferred to Plymouth Rock fowls from the same stock as the first case, but transplants now grow in most varieties of fowl.

Experiments with the chicken sarcoma of Rous have been the bases for alleged reports of the discovery of a living organism that produces cancer, but the State Institute has shown that extracts from a placenta or embryo may be used for the tumor extract in one stage of the experiment.

**Curability of Cancer** Is cancer curable? The answer to this question is similar to that regarding what was called "inflammation of the peritoneum" a generation ago, but what we now know to have been appendicitis. Most cases of

partments, and are making their own examinations of tissues which they formerly sent to the Institute. The constantly increasing interest shown by physicians in the diagnosis of cancer is a most favorable indication of the ultimate conquest of the disease.

The procedure of sending a sample of tissue to the Institute for examination is simple. The specimen is to be placed in a solution of one part of commercial formalin in four parts of water, and mailed to the Institute for the Study of Malignant Disease, 113 High Street, Buffalo, N. Y. A brief history of the case should also be sent with the specimen.

The Pathological Department makes complete autopsies on as many cases as possible. During the last year thirty-seven were made on patients who had died in the hospital, and on whom exact observations had been made. These cases have afforded unique opportunities for the study of the effects of treatment on various kinds of tumors.

The Department is always ready to supply microscopic slides and photomicrographs to investigators and teachers, and to welcome physicians who wish to study pathological conditions.

**2 The Department of Biological Chemistry and Clinical Pathology** The chemical work of the Institute is conducted by Dr. Carl F. Cori and three technical assistants. This Department carries out the routine analyses of patients in the hospital and dispensary, and makes studies in metabolism and other living processes. The scope of its activities is shown by the following table:

Wassermann reaction	1,200
Kahn precipitation tests	1,200
Neisser tests	600
Urine analysis	3,000
Kidney function tests	65
Sputum analyses	50
Bacteriological examinations	50
Gastric contents	40
Stools	10
Fluids from chest and abdomen	15
Spinal fluids	6

Several papers concerning work done in this department were presented before scientific societies.

During the past year, this Department has made special studies regarding the infectious nature of the chicken sarcoma of Rous, and in the metabolism of tumor cells, especially their utilization of carbohydrates and oxygen.

**3 The Department of Biology** The animal experimentation work of the Institute is conducted by Millard C. Marsh, M.S., and two technical assistants. This Department is located on a large farm owned by the State in Springville, thirty miles south of Buffalo. This site was

chosen for the special purpose of studying cancer in trout. During the past year the Department has investigated the effects of massage in hastening the development of breast tumors in mice, and has tested the injections of selenium and colloidal lead in the cure of cancer. It has also carried on an extensive series of experiments in which mice are kept in an atmosphere under compression.

The Department is also conducting tests on the effects of dyes injected into the circulation. Those physicians who attended the Exhibit and the State Medical Society will recall the white mice whose ears and feet were brilliantly blue from the injection of methylene blue into the blood. While these experiments have not pointed the way to a cure of cancer, they are valuable as indicating the dosage of various chemicals which a mouse can endure.

**4 The Hospital and Dispensary** The examination and treatment of cases of cancer is an important activity of the work of the Institute. This work is in charge of Dr. Bernard F. Schreiner, and a staff consisting of six clinical assistants, Drs. L. C. Kress, J. B. Mulholland, C. C. Herger, C. A. Quinn, R. C. Wende, and J. W. Kohl. Specialists on the staff are Dr. E. M. Watson, Urologist, Dr. L. M. Smith, Laryngologist, and Dr. K. F. Eschelman, Esophagoscopist.

The hospital has twenty-five beds, and is designed for the accommodation of dispensary cases who require continuous observation or treatment. The 1926 report of the Department states:

"During the past year there have been admitted for examination 844 new patients. Of the 844 new patients 186 were not accepted for various reasons. Some of the patients did not have malignant disease. Other cases, with malignant disease, were beyond any possibility of even palliative treatment, while still others would not comply with the regulations required for admission to the Institute. The total number of dispensary visits between January 1, 1926, and December 31, 1926, was 7,600.

"On December 31, 1926, there were on file 5,826 complete case histories of which 1,396 were current ones."

Concerning the advanced or incurable stage in which the patients are often received, the report says:

"Unfortunately, some of the patients that come to the Institute have been inadequately treated by radiation by persons not entirely competent to give this treatment. Ofttimes we are unable to do anything for these patients at the time on account of the radiation they have already had and because of the delay valuable time is lost. It is hoped that by a wide distribution of our methods, as given in our publications, we will obviate this deplorable condition."

been tried out and the grains of truth separated from the chaff of theory, and exploitation. The work of the Institute is the recognized standard by which all cancer research and methods of treatment are judged. Its work has been expanded until at present the appropriations for maintenance alone is \$150,000 annually.

The Institute was originally placed under the Department of Health, and then it was made independent under its own trustees, but within a year it has returned to the jurisdiction of the Department of Health, with its Director practically in full charge of all its activities.

The success of the Institute has been largely due to its Directors, who, fortunately, have never been hindered or impeded in their work. The first Director was Dr. Harvey R. Gaylord, who was peculiarly well fitted for the position by temperament and training. On his death in 1924 he was succeeded by the present Director, Dr. Burton T. Simpson, who had been connected with the Institute almost from 1910, and was in charge of the diagnostic work of the institution.

Another great factor in the success of the Institute has been the cooperation of the physicians throughout the State, and this in turn is the reflection of the friendly attitude of the Staff. Visiting physicians have always been welcomed, and have been given friendly assistance, as they have sought advice and information. The Directors and members of the Staff have always been ready to respond to requests to give papers before medical societies, and have shown the happy ability and inclination to make their addresses simple and practical. The Institute has a friendly attraction for physicians.

The fortunate choice of a Director was a great element in the successful growth of the Institute. Concerning Dr. Gaylord's peculiar adaptability for his position as Director, the Annual Report of the Institute for 1924 contains the following paragraphs written by his successor, Dr. Burton T. Simpson:

"Dr. Gaylord was one of the pioneers in laboratory cancer research. He has left a record of much work accomplished, but to my mind the greatest monument which he has left is the State Institute for the Study of Malignant Disease. Had it not been for his indefatigable and persistent efforts when appropriations were difficult to obtain, the laboratory would have succumbed. Not only did he maintain it, but he built it up to a magnificent institution which is favorably known throughout the scientific world.

"He had a wonderfully broad acquaintance with men throughout the scientific world and had many very warm friendships. He was generous to a fault. Returning from abroad he always brought back a gift for each member of the Institute.

"His whole life was centered about the Institute and even during the last weeks of his ill-

ness when he was very low, he was making plans for work which he thought was desirable."

While the Institute was founded primarily for impersonal research, it has extended its field of investigation to include the treatment of cases. One of its great functions is to develop the means by which practising physicians throughout the State can apply the present scientific knowledge effectively in the cure of the disease. The work of suppressing cancer is conducted from three concentric spheres of influence. The central sphere is the Institute, which originates and standardizes the methods. The next sphere is composed of the practicing physicians and their associated helpers, the nurses and other professional assistants. The outer sphere is composed of the people any one of whom may possibly be a cancer patient.

The Institute and similar groups of investigators are the producers of knowledge, physicians are the salesmen, and the people are the buyers and users of the knowledge. The development of the means of educating the people regarding cancer is as important as scientific research into the nature of the disease, and this phase of the cancer problem receives its due share of attention in the Institute.

The Institute is conducted under seven departments, each in charge of a chief.

**1 Department of Pathology** The Department of Pathology is conducted by Dr. Alphonse A. Thibaudeau, assisted by Dr. Gerty T. Cori, and five technicians. This Department is the one with which physicians are the most familiar because its diagnostic service is at the disposal of physicians. Any doctor can send a specimen of tumor to the Institute and receive a prompt report regarding its nature. About thirty specimens are received on every working day of the year. Each one is sectioned and stained, and a number of slides from it, are filed away for future reference. Specimens from over 55,000 cases are on file, and include almost every known form of cancer or cancer-like material.

The following table from the yearly report of 1926, shows a summary of the year's work of the Department:

Total number of cases,	7,966	
Malignant		
Carcinoma	1,371	
Sarcoma	202	1,573
<hr/>		
Non-malignant		
Benign	2,152	
Inflammatory	4,076	
Borderline	117	
Insufficient	48	6,393
<hr/>		

The diagnostic work of the Department is constantly increasing at the rate of ten or fifteen per cent yearly. At the same time the larger hospitals are establishing their own pathological de-

pathology was furnished by the laboratories of the Buffalo City Hospital under the direction of Drs William F Jacobs and Alvin G Foord. It presented about ninety museum specimens of various organs showing different types of malignant growths. It exhibited most of the malignant tumors commonly found in the various locations, including those in the mouth, throat, chest, abdomen, lymphatic apparatus, cranial cavity and of the bones, all collected from the surgical and autopsy material of the Hospital. Several specimens of lung carcinomata mounted with the entire lung and mediastinum intact were particularly striking.

Various types of carcinoma of the stomach were also shown, including several of the common types fungating medullary growths, Polypoid types, colloid cancers and scirrhus varieties showed graded degrees of involvement, including some showing extension throughout the entire organ with marked shrinkage of the viscus.

Several primary liver cancers were shown, some of the liver cell variety and others derived from biliary ducts. Livers showing metastatic growths were displayed for comparison.

Carcinomata of the colon and rectum, and several of the uterus, ovary, esophagus, and tongue, composed a large part of the exhibit.

Several brains showing gliomata, and others showing carcinoma or sarcoma metastases, were also shown. Varieties of sarcomata and carcinoma metastases into the vertebral column represented the greater part of the exhibit devoted to malignant tumors of bone. Several lymphosarcoma specimens from the chest and neck and Hodgkin's disease specimens, comprised the display of fatal lymph gland new growths.

The remaining portion of the exhibit of gross specimens consisted of hypernephromata, carcinomata, mixed tumors of the kidney, bladder and prostate cancers, and rare tumors of various organs.

Several bottles of fluids from cases of carcinomatosis of the pleural and abdominal cavities, and specimens of gastric juice from cases of cancer of the stomach, were also on display. Microscopic smears of the sediments of these were demonstrated. Microscopic sections of most of the tumors on display grossly were on hand and some of the same demonstrated.

**2 X-ray Films** An exhibit from the X-ray Department of the Buffalo City Hospital, under the direction of Dr Clifford R Orr, and correlated by Dr Stewart A Ver Nooy, was composed of eighty-eight films, displaying malignant tumors in various organs and bones of the body.

In order to correlate the X-ray Exhibit with the pathological specimens on display, nearly all of the films shown were from cases, the gross

and microscopic specimens of which were demonstrated by the Pathological Department.

Among the malignancies of bone were films showing periosteal and osteo sarcoma, multiple myeloma, and metastatic processes.

There were about fifty films showing malignant lesions in the gastro-intestinal tract, the films of the stomach and colon showing particularly a wide divergence in the types of deformity produced by the growths.

Films showing primary and secondary growths in the lung numbered about twenty-five. Three chest films showed lymph sarcoma, two cases being children and one an adult.

There were two very interesting series of chest films, the early roentgenograms in both cases showing the entire hemi-thorax obliterated by fluid. Later roentgenograms, after removal of the fluid and the injection of a small amount of air revealed, in one of the cases, a single large tumor originating from the mediastinum, and in the other cases, numerous circumscribed masses from one to eight centimeters in size of about the same density as bone and apparently originating from the pleura.

Another series of chest films from one patient demonstrated the growth of a lung tumor over a period of seven months.

There were several chest films, showing new growths in the lung of the infiltrating type and several others showing isolated metastatic nodules.

Among the kidney films, there were two pyelograms demonstrating hypernephroma, the chest films from the same individuals showing the metastatic processes in the lungs.

**3 Microscopic Pathology** A large series of slides illustrating the microscopic pathology of cancer was arranged by Dr Burton T Simpson, Director of the State Institute for the Study of Malignant Disease, and Drs Alvin G Foord, William F Jacobs, from the Pathological Department of the Buffalo City Hospital. These were shown on twenty microscopes loaned to the Medical Society of the State of New York by the Spencer Lens Company of Buffalo.

**4 Frozen Sections** The rapid "Table Diagnosis" of fresh specimens by means of frozen sections was demonstrated by Dr Alphonse A Thibaudeau, Chief of the Pathological Department of the State Institute for the Study of Malignant Disease, and his assistants, Miss Irma Miller and Mr Eugene Burke.

**5 Animal Experimentation** Methods of investigating cancer on laboratory animals was demonstrated by Millard C Marsh, Chief of the Department of Biology of the State Institute for the Study of Malignant Disease. A striking demonstration was that of injecting dyes into the circulation through a vein in the tail of a

Among the special studies made in the hospital during 1926 were the effects of sodium oleate, colloidal lead, liver extracts, and a mistletoe preparation, all of which had been widely reported as cancer cures, and found to be of no benefit. Concerning these experiments, the 1926 report says

"While it takes only a few words to report on the results of these investigations, yet days and weeks were needed in carrying out the individual experiments."

The hospital staff performed 70 major operations during 1926 and 520 of a minor nature, including the removal of tissue for diagnosis. A great number of treatments with X-ray and radium were also given, and their results carefully recorded.

**5 The High-Voltage X-ray Department** Radiation ranks next to surgery as an efficient therapeutic agent in cancer, and is extensively used in the Institute. The Radiation Department is in charge of Dr. Walter L. Mattick, assisted by Dr. Anna M. Schulz and three technicians. Concerning this Department, the report of 1924 says

"The work of the X-ray Department consists of locating and outlining definitely the malignant lesions, the determination and measurements of the doses and the application of high power X-ray to the patients to whom this type of therapy is most suited."

"Besides the routine treatments, research problems are undertaken in collaboration with other departments of the Institute."

"It is now recognized that there is little or no difference in the biological effect, whether one uses radium or X-ray. The choice resolves itself into a question of the most convenient and efficient method of application."

Radium is applied by means of its emanation, which is taken from the radium salt daily and placed in sealed tubes of glass, platinum, or gold. The strength of each tube is tested so that the dosage of the emanation may be accurately estimated. (See page 1045.)

The work of the X-ray Department is marked by exactness. The penetration of radiant rays and their effects on the skin and tissues have

been accurately investigated, and the direction of the application to deep-seated tumors have been plotted so that the exact amount of radiation reaching every part of a tumor and the surrounding tissue may be known. Thus the effects of excessive single doses may be avoided, while effective quantities may be applied.

**6 Physics Department** The preparation of radium emanation and the accurate measurement of the output of X-ray bulbs is the work of the Department of Physics. This Department is in charge of M. C. Reinhard, M.S., and three assistants, together with an instrument maker, a mechanic, and a glass blower. These workers have charge of the radium owned by the Institute, and they prepare the tubes or seeds containing the emanation which is used in the treatments.

The workers also test the output of radiant energy of the X-ray machines, and construct elaborate pieces of apparatus for measuring and regulating radiant rays and emanations. Their work is highly technical, and yet practical, and is essential in securing accuracy and uniformity in the dosage of radiant energy.

**7 Radiography and Photography** The preparation of photographic records is the work of the Department of Radiography and Photography, which is in charge of Dr. L. C. Kress, assisted by a photographer. This Department makes X-ray plates and films, and photographs patients and tumors, and makes photomicrographs, lantern slides and charts.

**The Library** The library of the Institute is in charge of Miss Scheffler. It contains 3,453 volumes, while 48 periodicals are on file. It maintains bibliographies on subjects relating to cancer, and conducts researches into the literature of malignant diseases.

**Morale** The usefulness of an institution depends very largely upon the morale of its staff, two elements of which are enthusiasm and generosity. The spontaneous exhibition of these two qualities by the members of its staff is a great element in the maintenance of the universal support which the Institute receives from the physicians of New York State.

## THE EXHIBIT AND DEMONSTRATION

To arrange a cancer exhibit that makes a strong appeal to the average physician is difficult for two reasons.

1 The fundamental principles of cancer control are fairly well known to most practitioners of medicine, and physicians are likely to assume a we-have-seen-that-before attitude.

2 Skill in diagnosis and treatment consists largely in attention to a multitude of details whose comprehension requires intensive study.

However, the cancer exhibit of the Medical Society of the State of New York was of great value in illustrating the points which are now being emphasized by the State Institute for the Study of Malignant Diseases, the American Society for the Control of Cancer, and other organizations engaged in cancer control.

The Exhibit was arranged under the following departments:

**1 Gross Pathology** An exhibit of gross

pathology was furnished by the laboratories of the Buffalo City Hospital under the direction of Drs William F Jacobs and Alvin G Foord. It presented about ninety museum specimens of various organs showing different types of malignant growths. It exhibited most of the malignant tumors commonly found in the various locations, including those in the mouth, throat, chest, abdomen, lymphatic apparatus, cranial cavity and of the bones, all collected from the surgical and autopsy material of the Hospital. Several specimens of lung carcinomata mounted with the entire lung and mediastinum intact were particularly striking.

Various types of carcinoma of the stomach were also shown, including several of the common types fungating medullary growths, Polypoid types, colloid cancers and scirrhus varieties showed graded degrees of involvement, including some showing extension throughout the entire organ with marked shrinkage of the viscus.

Several primary liver cancers were shown, some of the liver cell variety and others derived from biliary ducts. Livers showing metastatic growths were displayed for comparison.

Carcinomata of the colon and rectum, and several of the uterus, ovary, esophagus, and tongue, composed a large part of the exhibit.

Several brains showing gliomata, and others showing carcinoma or sarcoma metastases, were also shown. Varieties of sarcomata and carcinoma metastases into the vertebral column represented the greater part of the exhibit devoted to malignant tumors of bone. Several lymphosarcoma specimens from the chest and neck and Hodgkin's disease specimens, comprised the display of fatal lymph gland new growths.

The remaining portion of the exhibit of gross specimens consisted of hypernephromata, carcinomata, mixed tumors of the kidney, bladder and prostate cancers, and rare tumors of various organs.

Several bottles of fluids from cases of carcinomatosis of the pleural and abdominal cavities, and specimens of gastric juice from cases of cancer of the stomach, were also on display. Microscopic smears of the sediments of these were demonstrated. Microscopic sections of most of the tumors on display grossly were on hand and some of the same demonstrated.

**2 X-ray Films** An exhibit from the X-ray Department of the Buffalo City Hospital, under the direction of Dr Clifford R Orr, and correlated by Dr Stewart A Ver Nooy, was composed of eighty-eight films, displaying malignant tumors in various organs and bones of the body.

In order to correlate the X-ray Exhibit with the pathological specimens on display, nearly all of the films shown were from cases, the gross

and microscopic specimens of which were demonstrated by the Pathological Department.

Among the malignancies of bone were films showing periosteal and osteo sarcoma, multiple myeloma, and metastatic processes.

There were about fifty films showing malignant lesions in the gastro-intestinal tract, the films of the stomach and colon showing particularly a wide divergence in the types of deformity produced by the growths.

Films showing primary and secondary growths in the lung numbered about twenty-five. Three chest films showed lymph sarcoma, two cases being children and one an adult.

There were two very interesting series of chest films, the early roentgenograms in both cases showing the entire hemi-thorax obliterated by fluid. Later roentgenograms, after removal of the fluid and the injection of a small amount of air revealed, in one of the cases, a single large tumor originating from the mediastinum, and in the other cases, numerous circumscribed masses from one to eight centimeters in size of about the same density as bone and apparently originating from the pleura.

Another series of chest films from one patient demonstrated the growth of a lung tumor over a period of seven months.

There were several chest films, showing new growths in the lung of the infiltrating type and several others showing isolated metastatic nodules.

Among the kidney films, there were two pyelograms demonstrating hypernephroma, the chest films from the same individuals showing the metastatic processes in the lungs.

**3 Microscopic Pathology** A large series of slides illustrating the microscopic pathology of cancer was arranged by Dr Burton T Simpson, Director of the State Institute for the Study of Malignant Disease, and Drs Alvin G Foord, William F Jacobs, from the Pathological Department of the Buffalo City Hospital. These were shown on twenty microscopes loaned to the Medical Society of the State of New York by the Spencer Lens Company of Buffalo.

**4 Frozen Sections** The rapid "Table Diagnosis" of fresh specimens by means of frozen sections was demonstrated by Dr Alphonse A Thibaudeau, Chief of the Pathological Department of the State Institute for the Study of Malignant Disease, and his assistants, Miss Irma Miller and Mr Eugene Burke.

**5 Animal Experimentation** Methods of investigating cancer on laboratory animals was demonstrated by Millard C Marsh, Chief of the Department of Biology of the State Institute for the Study of Malignant Disease. A striking demonstration was that of injecting dyes into the circulation through a vein in the tail of a

mouse The dye would spread through the circulation almost instantly, and would give the ears and feet the brilliant color of the dye used

**6 Clinical Cases** Five clinical cases and their X-ray films were shown by Dr Bernard J Schreiner, Chief of the Hospital Department of the State Institute for the Study of Malignant Disease

**7 Radium** Appliances for radium and radon therapy were shown by the Radium Chemical Company, New York City This included a demonstration of screening radium element tubes and needles, the use of steel needles and a display of glass, gold and removable platinum implants with the instruments employed to introduce them in tissues

**8 Endothermy.** Moving pictures showing methods of applying endothermy in the removal of tumors were exhibited by Dr George A Wyeth, of New York City

**9 Popular Movies** Two moving picture films for popular audiences were shown by Dr John M Swan, Rochester, State Chairman, American Society for the Control of Cancer One film shows a woman with a suspicious lump on her breast, Her husband heard of a doctor who was good in cancer cases This doctor applies a salve and advises rubbing The film ends with a funeral

The second film shows another woman consult-

ing her doctor who advises an immediate operation The examination of the tumor is shown with a positive report, and the film ends with the patient well and happy five years afterward

Statistical charts and specimens of popular literature were also shown

**Papers on Cancer** The afternoon was given over to a series of papers on Cancer The program was as follows

"Etiology of Cancer," Burton T Simpson, M D, Buffalo, Director State Institute for the Study of Malignant Disease, Buffalo

Discussion opened by Herbert A Smith, M D, Buffalo

"Cancer Research," William H Woglom, M D, New York City, Institute of Cancer Research of Columbia University

Discussion opened by Burton T Simpson, M D, Buffalo

"Diagnosis and Prevention of Cancer," Isaac Levin, M D, New York City, Director New York City Cancer Institute, New York

Discussion opened by William D Johnson, M D, Batavia.

"Treatment of Cancer," Bernard F Schreiner, M D, Buffalo, State Institute for the Study of Malignant Disease, Buffalo

Discussion opened by Douglas Quick, M D, New York City

These papers are published in this Journal beginning on page 1006

## THE MEMORIAL HOSPITAL

By JAMES EWING, M D, NEW YORK, N Y

**T**HE Memorial Hospital, 2 West 106th Street, New York City, was established in 1886 by Mrs Astor and Mrs Cullom, and named the New York Cancer Hospital The name was later changed to the General Memorial Hospital, and finally to Memorial Hospital for the Study of Cancer and Allied Diseases

For many years very little work on cancer was done at this hospital, owing to the lack of productive fields of study, but in 1912 Dr James Douglas gave the institution a considerable endowment and four grams of radium, on condition that cancer work should be resumed and an affiliation established with Cornell University Medical College The offer was accepted and the systematic development of clinical cancer research was begun Numerous small, and several substantial bequests have enabled the hospital to gradually increase its equipment and the clinical and laboratory staffs The latest of these gifts are those of Mr Edward S Harkness, of \$250,000 for the purchase of four grams of radium, and of Mr John D Rockefeller, Jr, of \$60,000 a year for five years to enlarge the general activities of the hospital New build-

ings added include the Douglas Laboratory, a modern X-ray building and equipment, and a nurses' home given by the Misses Douglas

The main function of this hospital has been conceived to be the clinical study of cancer and the development of modern service to the cancer patient The clinical organization takes the form of seven special departments, each conducted by specialists who devote most of their time to the diagnosis and treatment of special varieties of cancer These departments function under the direction of the Medical Board The hospital is well equipped for the treatment of cancer by surgery and the physical methods, but the bed capacity is inadequate to meet demands

The education of medical students is conducted to the fullest extent permissible by medical curricula, but is regarded as still very inadequate

An effective social and follow-up system have been established at considerable expense, defrayed by a special committee of women

The laboratory departments include pathology, chemistry, physics and biology, and the total laboratory staff numbers 16 The equipment of

these departments is fairly complete but the work is considerably restricted by lack of space. The studies from the departments are collected in volumes published annually.

The total bed capacity of the hospital is about 110. The out-patient service is very large, since most of the favorable stages of cancer are found in walking cases.

## INSTITUTE OF CANCER RESEARCH, COLUMBIA UNIVERSITY

By FRANCIS CARTER WOOD, M.D., NEW YORK, N. Y.

THE Institute of Cancer Research was founded by George Crocker. By a will executed February 3, 1910, he left to the Trustees of Columbia College in the City of New York the money which should accrue from the sale of his New York house and his country place at Darlington, New Jersey. The funds obtained from the sale of these two properties amounted to \$1,455,000. The terms of the will were that the income "shall be applied in such manner as said Trustees may from time to time determine, in the prosecution of researches as to the cause, prevention and cure of cancer, and should the progress of science at any time make the prosecution of further researches in regard to cancer unnecessary, then the income of said fund may be used as said Trustee may from time to time determine in the prosecution of other researches in medicine and surgery and in the sciences allied thereto, with a view of preventing and curing diseases and of alleviating human suffering."

The Trustees constituted a Board of Managers, directing them to spend the income of the Crocker Fund to carry on the work of cancer research. This Board was composed of the President of the University and Dean of the Medical School ex-officio, two trustees to be elected, two members of the Faculty likewise elected, and the executive officer, at present, Dr. Francis Carter Wood. A building was constructed by the University at 116th Street and Amsterdam Avenue to house the work of the Fund, which was opened in 1913. Since that time investigations on various phases of the cancer problem have been carried out. Among these investigations may be enumerated studies to determine the necessary dose of  $x$ -ray to kill animal tumors and healthy tissues, and to determine these as a function of the wave-lengths of  $r$ -ray, and it has been shown that for equal quantities of  $r$ -ray measured in the usual fashion by an open ionization chamber, all wave-

lengths are equally effective. This has also been extended to radium, using the filters ordinarily used in practice. The killing effects of radium and  $x$ -ray were found to be proportional to the quantity and time of exposure within the limits of one to eight. More recently this work has been confirmed by investigations on the eggs of the fruit-fly *Drosophila*. Other phases of the work have been the investigation of the effect of making a biopsy on an animal tumor, which is shown not to facilitate metastasis, and also to study the effect of massage, which has been found to increase in many instances the number of metastatic particles.

From the beginning, plans were made to investigate the genetic aspect of cancer, and a long series of studies are now in progress on the heredity factors, which may or may not underlie the susceptibility of the white rat to *Cysticercus* sarcomata. In the course of this experiment it was found that the *Cysticercus* could produce seventeen varieties of tumors in the liver, the most frequent being the spindle or polyhedral-cell sarcomas, but chondromas, osteosarcomas, and liposarcomas have also been produced.

A whole series of studies on the relation between ionization measurements and the energy output of tubes have also been made.

In addition, an attack has been made from various angles on the question of the nature and source of immunity which permits an animal to produce a spontaneous cure of its own tumor, in the hope that some practical application might ultimately come to the human race.

Lastly, the Institute of Cancer Research has supplied animal tumors to a large number of laboratories, makes animal tissue diagnoses for those who desire, and has tested on request a variety of quack remedies, and it stands ready at any time to furnish technical information on the subject of cancer to those who need it.

## ETIOLOGY OF CANCER\*

By BURTON T SIMPSON, M D

Director, State Institute for the Study of Malignant Disease, Buffalo, N Y

**I**N every symposium on any subject it is customary to subdivide the subject into its component parts. Therefore, this symposium on cancer would not be classical if we did not start it with a consideration of the etiology. Unfortunately, I am not able to give you a definite specific etiology for this disease. The reason, according to my belief after an intensive study of the disease for 18 years, is that there is no definite specific etiological factor.

The three outstanding theories of the causation of cancer are

- 1 Infectious
- 2 Cohnheim's
- 3 Virchow's

Cohnheim's theory proposed that cancer originates in groups of misplaced embryonic cells.

Virchow believed that cancer was the result of a chronic insult or injury to normally existing cells.

Naturally, it would simplify the question if we could isolate some microorganism from cancer which would conform to Koch's postulates. In the past 25 years claims have been made by different investigators of having discovered a specific microorganism as the cause of cancer. These claims have not been substantiated by other research workers, and in most cases, the discoverer has been obliged to acknowledge that he was mistaken.

An immense amount of work has been done to prove or disprove that cancer is an infectious disease. Careful analysis of this work forces me to the conclusion that there is no evidence that cancer is caused by a specific organism.

The incidence of the disease, the absence of the usual manifestations of infection, as temperature, blood changes, immune reactions, etc., would seem to argue against cancer being of an infectious nature, besides the inability of anyone to isolate an organism which would stand the scrutiny of subsequent investigation.

While Cohnheim's theory may apply to some rare cases of tumor formation, the majority of cancer as we see it clinically, originates from normally placed cells. Therefore, for practical purposes, Cohnheim's theory can be eliminated from this discussion.

By exclusion we are forced to consider the merits of Virchow's theory and to analyze it to see if we can make it coincide with clinical experience and the findings of cancer research. Undoubtedly, cancer is the result of some effect upon cells which causes them to take on excessive and unlimited growth energy. Primarily, growth

was the chief function of cells. But as these cells reach their normal stage, growth capacity decreases and in some cases becomes nil. Secretion or some special activity becomes prominent and according to the degree of special functional activity that the cells assume, reproduction is in inverse proportion. However, all cells retain growth potentiality and if sufficient stimulus is brought to bear upon them they will react by reverting to the growth phase.

The exact mechanism of this is not known. It is probably a complicated biological phenomenon.

The supporter of the parasitic theory believes that an organism invades the cell and in its division, produces some substance which stimulates the cell to divide.

Cohnheim believed that all cancer cells were originally embryonic cells and, therefore easily stimulated to proliferate.

### EXPERIMENTAL CANCER

Observation of certain types of clinical cancer lead investigators to try to produce this disease artificially on the lower animals. The fact that a number of the early workers with the X-ray developed cancer upon areas which had been continuously exposed to X-ray radiations suggested this agent as a possible one for the experimental production of cancer. Clunet succeeded in producing sarcoma on the backs of rats by interrupted exposures continued for a long time. However, not all the rats so exposed developed cancer.

Because aniline workers frequently have cancer of the bladder, coal tar, from which aniline products are derived, seemed a logical substance to try. Virchow's theory presupposed a chronic or continued injury to a group of cells. This injury apparently destroys some of the cells and new ones are reproduced to fill in the deficit. This process repeats itself until finally a crop of cells are generated which have tremendous growth capacity and invade the neighboring tissues in all directions. Thus by continued insult, normal cells are aggravated into becoming what we call cancer cells. The injurious agent may be one of several kinds, viz, chemical, toxic, actinic, mechanical, thermic, etc.

For the artificial production of cancer, Yamagawa, a Japanese investigator, succeeded in producing cancer on the rabbit's ear by painting this organ with coal tar every few days for a period of many months. Since Yamagawa's report appeared, his work has been reproduced by other investigators in nearly all parts of the world, both on rabbits and mice.

Borrell observed sarcoma of the liver of rats,

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 12, 1927.

associated with cysts of this organ, caused by the embryonic stage of the tape worm of a cat. Bullock and Curtis fed rats with eggs of the cat's tape worm and succeeded in producing artificial sarcoma of the liver in a large proportion of the rats so fed.

In Egypt, the natives become infested with a hematobium which deposits its eggs in the mucosa of the bladder. Cancer of this organ is relatively frequent in these people. Microscopic examination of sections of these tumors shows the presence of eggs adjacent to the proliferating cancer cells.

Fibiger of Copenhagen has succeeded in producing cancer in the stomach of rats by feeding to these animals cockroaches which were infested with the embryos of a nematode. The embryos when liberated in the rat's stomach burrow into the mucosa and set up a reactive inflammation. In a certain number of these rats the inflammatory reaction is followed by cancer.

Blumenthal has produced tumors by injecting cultures of non-pathogenic bacteria into rats. This procedure must be repeated many times and continued for a long period. However, only a small percentage of the animals treated react by cancer formation.

Narat has produced cancer in mice by long continued painting of their backs with HCl and KOH.

Kazama, using guinea pigs and rabbits, was successful in producing cancer in the gall bladder, stomach and urinary bladder of these animals by a combination of mechanical and chemical irritation. He also succeeded in producing cancer of the gall bladder in guinea pigs, by pure irritation, using human gall stones.

Thus we see that cancer can be produced experimentally by subjecting normal cells to chronic injury. That this injury may be of a variety of types, chemical, actinic, toxic, mechanical, etc. One fact stands out in the experimental production of cancer, as it also does in clinical cancer. That is, that all the animals subjected to any of the various irritants do not become cancerous. We must therefore, conclude that in the animals whose cells do not react to chronic injury by unlimited proliferation, there must be some factor which prevents this reaction.

Considerable work has been done to try to show immune or resistant factors, but this work has been consistently negative. It is most probable that those individuals who become cancerous are born with cells which are unstable, that is, they may be considered as cells that retain the potential growth propensity to a higher degree than do normal cells.

Apparently these susceptible cells are not widespread throughout the body but are usually limited to one viscus as is indicated by the infrequency of multiple cancer. These facts of inher-

ited tendency or susceptibility are sustained by the results obtained in experimental research. It is possible, by inbreeding the offspring of cancerous parents, to obtain a strain of animals in which there is a high incidence of cancer. This is especially true of cancer in the breast of white mice. We have one strain in which the females will show 50% of breast cancer and another strain which shows 94%. The factor of susceptibility is markedly brought out by selective inbreeding.

To summarize these facts, we may say that for practical purposes the majority of clinical cancer is caused by chronic insult or injury to a group of cells, which by virtue of their being unstable, react to injury by unlimited proliferation.

Although in some cases the injury is crude and easily recognized, it should not be concluded, that in others where the injury is not so apparent, it does not exist. For there may be insults to cells which are so subtle that we cannot recognize them with our present methods.

It might be advantageous to consider some concrete cases, to learn if these tally with the above outlined theory of the cause of cancer.

### (I)

First we will take the elevated pigmented naevus. Here we have to do with embryonic cells which notoriously react to injury by excessive proliferation. There are two types of pigmented naevi, (1) the flat (2) the elevated. These are both composed of the same type of cells. However, the flat naevus rarely, if ever, undergoes malignant change. The reason is that this type is not commonly subjected to chronic injury. On the other hand, elevated pigmented naevi are often the originating focus of melanoma, and the history usually shows that they were subjected to chronic injury.

### (II)

#### *Cancer of the Lip*

This lesion commonly occurs in pipe or cigar smokers and its site usually corresponds to the area where the pipe or cigar is held. Very commonly the malignant change is preceded for a long period by a patch of leucoplakia. The mechanism consists probably of a proliferative reaction on the part of the cells to protect the delicate underlying tissues from the products of the tobacco. Some cases of cancer of the tongue and larynx have a similar etiologic history.

### (III)

#### *Cancer of the Tongue*

Malignancy in this organ usually occurs along the margin. Careful examination will nearly always reveal ragged or sharp edged teeth corresponding to the location of the cancer. The

sequence of events are as follows First the ragged edged teeth cause a destruction of the adjacent cells with the production of an ulcer A new crop of cells is produced These in turn are likewise destroyed and the process repeats itself until after a while a crop of cells is produced which has tremendous growth capacity and they invade the tissues in all directions, in other words, they have become cancer cells The same mechanism can be applied to cancer springing from the edges of chronic tubercular, syphilitic or varicose ulcers, or from chronic dermatitis

#### (IV)

##### *Cancer of the Breast*

Here the type of insult is not so apparent Formerly we have laid stress upon the effect of mechanical injury as caused by corset steels, trauma, etc., or have concerned ourselves with the association of chronic mastitis While this latter condition is very frequently associated with cancer of the breast, it is necessary of course, to learn the cause of chronic mastitis Some interesting laboratory experiments might be mentioned here For instance, if we remove the ovaries from the mice of our high cancer strain before puberty, none of them will develop cancer of the breast This procedure prevents secreting cells to be formed in this organ

Dr Bagg of New York has made some interesting observations in regard to breast cancer in mice He has a strain of mice in which only 5% of the females will develop spontaneous cancer of the breast If he breeds the mice and immediately removes the young after birth, thus preventing suckling, and repeats this procedure several times, the mice so treated will develop cancer at an incidence as high as 87% The decomposed stagnant milk remaining in the breast for a long period evidently stimulates the susceptible cells to excessive proliferation

In this connection it might be stated that no one has ever reported cancer as occurring in the mammary gland in the cow

Another clinical observation might also be offered in support of this laboratory finding Cancer of the breast ranks second in malignant disease of English and American women, while it is next to last in Japanese women It is well

known that the Japanese women consistently nurse the offspring

#### (V)

##### *Cancer of the Uterus*

Ninety-eight per cent of cervical cancer occurs in women who have borne children The normal ratio of single to married women in the United States is about one to eight Therefore, one can see that child birth has some intimate relation to cancer of the cervix The fundamental factor must be associated with cervical tears One can easily visualize the loss of continuity of the surface epithelium and its incorporation in the scar tissue The mechanical action of contracting scar tissue may be an important factor in stimulating the imprisoned cells to proliferate to free themselves

Undoubtedly, chronic cervicitis and the associated production of low grade toxins is a factor in some cases in stimulating susceptible cells to excessive proliferation

Adeno-carcinoma of the corpus uteri is intimately associated with mechanical disturbances produced by the presence of fibroid tumors

The time limit on this paper will not permit me to go into detail concerning all the types of cancer that might be made applicable to this conception of etiology However, I might mention the relation between gall stones and cancer of the gall bladder, cirrhosis of the liver and hepatic cancer, gastric ulcer and cancer of the stomach Also that the common sites of intestinal cancer correspond to the constrictions and flexures which are subjected to mechanical injury The chimney sweep's cancer of the scrotum, aniline worker's cancer of the bladder, and cancer of the mouth due to chewing of the betel nut are also examples which are familiar to you all

This conception of the etiology of cancer is to my mind a very practical and hopeful one for it premises, in most cases, a period more or less prolonged, in which we may recognize a pathological condition before it has actually become cancerous, and as the removal of the cause is one of the first principles in medical practice, a recognition and acceptance of the relation of chronic injury to the production of cancer prepares us to practice our art in the highest degree, namely, the prevention of disease

## MODERN CANCER RESEARCH\*

By WM H WOGLOM, M D, NEW YORK, N Y

From the Institute of Cancer Research Columbia University, New York.

AFTER it had been shown that tumors can be transplanted from animal to animal, the observational study of cancer could be supplemented by the experimental method. Almost the first question to be attacked was the vitality of the cancer cell under various conditions such as heat, cold, exposure to different chemicals, and so on, in the hope that some characteristic might be discovered which would give a clue to treatment. All these experiments failed, however, as the microscope had failed, to show any constant appreciable difference between the cancer cell and its normal prototype.

But because the question is so fundamental, experiments of this type have been continued, growing more and more rigorous as time goes on. The most recent in this field are those of Warburg and his associates, who have been investigating the respiration of the cancer cell.

Warburg had previously determined that after fertilization the sea-urchin egg requires six times as much oxygen as sufficed in its resting stage, and it occurred to him that a similar increase in oxygen need might be expected in the case of the cancer cell, to furnish the energy necessary for its vigorous proliferation. But to his great surprise, the amount consumed turned out to be actually smaller than that used by the normal liver and kidney cells with which he had compared it. This result was so startling as to justify the provisional assumption that the Ringer's solution in which the cells had been immersed during their examination did not contain suitable material for combustion. When glucose was added, however, respiration came to a standstill. Thus, Warburg found, was because lactic acid was produced by a splitting of the glucose, more than a hundred times as much appearing as was set free by most of the normal tissues investigated.

Now lactic acid is produced by normal cells, too, but their respiration suffices to remove it, whereas that of the cancer cell does not. Thus in muscle, for example, the following cycle takes place—1 Splitting of glucose to lactic acid. 2 Reconversion of lactic acid to glucose in the presence of oxygen. A certain mould investigated by Pasteur acts in the same way, and stops splitting glucose as soon as oxygen becomes available.

The cancer cell behave like neither of these, for oxygen does not stop the splitting reaction, glycolysis and oxidation go on together, as they do in a yeast cell. In this respect the cancer cell may be said to resemble a suffocating normal cell, and Warburg has, in fact, suggested that cancer may originate in a group of cells that have

been deprived of sufficient oxygen and have gradually learned to do without it.

Although Warburg's experiments have been confirmed *in vivo*, by the Coris, there is still considerable doubt of their ultimate significance. At any rate, Murphy and Hawkins were unable to duplicate Warburg's results with every tumor investigated. It may be, too, that this double respiration will prove to be a property of young, growing cells, rather than a characteristic of the cancer cell. Nevertheless, the value and importance of Warburg's work should not be minimized, for any information regarding normal growth may prove to be of use in elucidating the problem of malignant growth.

Another way of approaching the problem of neoplasia is to search for the immediate cause of the disease. Some of the contributing causes, such as age and chronic irritation, are already known, but neither of these is the immediate cause, for not all old people develop cancer, nor all those who have a chronic inflammatory lesion. It has been suggested by innumerable investigators that the immediate cause may be a micro-organism, yet after years of search none has been found that will satisfy all the requirements, and the majority of pathologists have been forced to the belief that cancer is probably not a parasitic disease.

But a short time ago a series of new experiments was published by Gye, of London, in which evidence was brought forward to show that certain tumors may be caused by some sort of organism. It is still too early to say just what these experiments really mean, so far, Gye's interpretation of them has not met with universal acceptance, nor have others been able to duplicate them in all their complex details.

His work was carried out with a sarcoma of the chicken, discovered some ten years ago by Dr Rous, of the Rockefeller Institute, a tumor which differs from mammalian new growths in that it can be transferred from fowl to fowl by means of a cell-free filtrate. The ordinary transplantable neoplasm of the mouse and rat, on the contrary, can be propagated only by the introduction of living and intact cells. Thus there is an agent of some sort in the filtered juice of this sarcoma which is able to cause tumors to develop in the normal tissues of the chicken, and Gye began his work by trying to find out what this might be. He found that something seemed to diffuse into broth cultures, for injection of the broth, even that from the top of the tube, was followed by the development of tumors, provided that it was introduced within the first week of cultivation. After this time, the broth lost its activity.

Although organisms will not live indefinitely

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 12, 1927.

in a culture tube, they can usually be depended upon to survive much more than one week, and Gye therefore suspected that the inactivity of old cultures was not due to the death of a living organism, but to the disappearance of a much more unstable substance—perhaps a chemical agent of some sort. He tested this hypothesis by killing the virus in a sand filtrate with chloroform, and adding the fluid to an old and inactive culture. Neither of the two fluids alone would produce a tumor, but when mixed they proved active. Thus he concluded that two factors are necessary for the production of a tumor—a virus, which can be killed by chloroform, and a specific chemical factor.

The details of his experiments need not be gone into at the present time. It will be enough to say that nobody has yet succeeded in reproducing all of his results, and that the importance of a living virus in the etiology of all tumors still remains to be proved. The most damaging fact so far offered in disproof of his hypothesis is the demonstration that sand filtrates can be reactivated by "cultures" not only of tumors but of various normal tissues as well.

It has been assumed for years that a method of inciting malignant growth at will would go far toward elucidating its ultimate cause, and it is but natural that attempts to produce tumors should have been prosecuted diligently. All were abortive, however, until Fibiger, of Copenhagen, reported that he had been able to produce cancer of the stomach in rats by feeding them on cockroaches infested with the larvae of a certain round worm. The worm settled down in the rat's stomach, and after a period of months a cancer appeared, presumably as a result of the chronic inflammation about the parasite. About the same time, Dr. Bullock, of the Crocker Institute, was experimenting with a tapeworm of the cat, which passes its larval form in the rat's liver. Here, again, the organism sets up a chronic inflammation which is eventually followed by sarcoma, provided the rat lives for the necessary eight months or so after infestation.

Although both of these methods marked an

extraordinary advance in our attack upon the cancer problem, they were not ideal, for the tumor was in an internal organ, so that it was impossible to determine just when it originated. A more convenient method, however, soon followed.

It had been known for a long time that laborers who handle soot, tar, or similar substances, are prone to develop cancer on the exposed portions of the body, and this fact was not lost sight of by those who were attempting to produce cancer experimentally. Dogs and rats were painted with tar, but in vain, and in the rabbit the results were no more encouraging. Had the earlier investigators known that not all species are susceptible to tar, and that a long period of painting is necessary before carcinoma appears, even in a susceptible species, the problem could have been solved forty years ago. But as ill luck would have it, those who had inadvertently hit upon the right species did not continue the irritation long enough, and those who kept on applying tar for a sufficient period had chosen the wrong species. It was the good fortune of Yamagiwa and Itchikawa not only to hit on a susceptible animal—the rabbit—but to have the necessary patience to continue their tar applications month after month, without any guarantee that their work would be rewarded. They were finally able to show that if a rabbit be painted with tar three times a week for about a year it will develop a cancer of the skin in the area painted, and Tsutsui soon afterward proved that the white mouse is even more susceptible.

The possibilities opened up by this discovery are obvious. Now, for the first time, it is possible to investigate the importance of age, to measure the intensity of the irritation that is required to produce cancer, to test the importance or unimportance of the endocrine glands, and so on. Furthermore, if it should prove possible to discover what constituent among the several hundred contained in tar is the active one, it may be that a number of industrial cancers can be eliminated. All these questions are under investigation in one laboratory or another, but the work is not far enough advanced to lend itself to a review.

## TREATMENT OF MALIGNANT DISEASE\*

By BERNARD F. SCHREINER, M.D., F.A.C.S.

State Institute for the Study of Malignant Disease, Buffalo, N. Y.

**I**N using the above title, I am not unmindful of how great an undertaking it is to try to set forth and elaborate the treatment of all types of cancer, but I will endeavor to correlate the facts which have been gathered from wide experience in the treatment of this disease, as well as the results of other workers. I believe it

essential to discuss the treatment of cancer under three separate headings, namely the prophylactic treatment, treatment of localized cancer, and the treatment of disseminated or wide-spread cancer.

Under the heading of prophylactic treatment, we must take into consideration the work which has proved by laboratory experiments that cancer can be produced by chemical, thermal and other irritations. I might here mention kangri

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 12, 1927.

stove cancer as caused by a thermal irritant, the irritation cancer caused by tobacco, betel nut, etcetera, and experimental cancer produced by prolonged irritation by the use of coal tar. With this in mind we must give consideration to the correction of all physical defects, so-called benign new growths or lesions due to trauma or irritation. All recognized pre-cancerous lesions, such as warts, naevi, or pigmented moles, chronic ulcers such as varicose ulcers, old lacerations of the female genitals and cervical tears with the accompanying cervicitis, phimosis in the male which does not permit the glands to be kept perfectly clean, hemorrhoids, bad hygienic condition in the mouth such as pyorrhea, decayed teeth, and abscessed roots, should be corrected by the proper treatment, surgically, or in exceptional cases such as warts and naevi, by desiccation, coagulation or irradiation. Tubercular lesions on the skin which result in much scarring and chronic changes in the epidermis may be dealt with in a prophylactic as well as a curative way by improved methods of treatment with Kromeyer lamps, and X-ray. Syphilis and its accompanying lesions, especially those on the mucous membranes, particularly the mouth with the production of leukoplacia, should be dealt with in a prophylactic way. There should be a thorough appreciation of the possibilities of malignant degeneration as a result of these lesions. Proper energetic specific treatment early in the course of syphilis will do much to avoid these scars. After the development of leukoplasias, especially about the oral cavity (thorough elimination of concomitant syphilis being borne in mind) the removal of all forms of irritation from tobacco, however used, should be insisted upon as well as the destruction of thickened leukoplasic areas by means of radium with very light filtration, or destruction by desiccation or even coagulation. This must necessarily be thorough, so as to eliminate the possibility of stirring up a leukoplacia which has already begun to undergo malignant change. It might be added that all forms of chronic disease which are amenable to surgery, such as gall stones, gastric ulcers, varicose ulcers and hemorrhoids should be dealt with surgically in order to eliminate as far as possible, those cases which possibly may undergo malignant change.

The prophylactic treatment of cancer would not be complete were we not to dwell a little upon the diseases of the breast, which by many are regarded as a menace or a source of danger due to the possibility of development of malignancy. I have particularly in mind the work of Bagg, in which he definitely proved, experimentally, at least, in mice, that the removal of the litters immediately after birth and thus allowing stagnation of the milk in the breast, raised very markedly the incidence of cancer in this organ. These experiments would seem to indicate that the proper hygiene of the breasts during lactation,

care of the nipple, the prevention of infections and mastitis with abscesses, are to be encouraged. The removal of all definite tumor formation or nodules in the breast such as cysts, whether papillary or otherwise, fibroadenomata, by proper surgical intervention, the treatment of eczematous condition about the nipple which leads to Paget's disease, by means of radiation, preferably unfiltered X-ray or radium, will do much toward the elimination of many cases of cancer of the breast.

In the treatment of local cancer we must necessarily remember that a variety of treatments will be efficient in eradicating disease, some of which have advantages over others from the standpoint of cosmetic results and no loss of time in the carrying out of treatment. At times two methods are of equal value in the hands of various physicians but one is obliged to choose one or the other in view of the fact that certain localities have a man extremely efficient in one type of treatment. In other localities there may be one familiar with the best technique of another agent. I have in mind radical surgery or endothermy as compared with inefficient X-ray or radium treatment, or the reverse, inefficient surgery with good radiation or endothermy. We will endeavor to discuss the treatment of localized cancer from the standpoint of location, type of growth and ability of the physician in a given locality.

Skin cancer, of which there are two varieties, basal cell epithelioma and the so-called squamous or pearl forming epithelioma, can be dealt with by five different varieties of treatment. I will discuss these methods in the order of their relative values, not being unmindful that there may be exception taken to this by many skilled surgeons. The small basal cell epithelioma is best treated by irradiation, with lightly filtered radium or unfiltered X-rays. I give preference from the standpoint of the ease of application, no loss of time, and the cosmetic result. It is true that desiccation or endothermy is very efficacious if performed thoroughly, being sure to go wide of the diseased area. In some types of basal cell epithelioma this method may be advantageous, especially where cartilage and fascia are involved. In basal cell epithelioma of the eyelids with involvement of the conjunctiva and even the contents of the orbit, the disease should be thoroughly eradicated by coagulation or endothermy followed with radiation by means of filtered radium or X-rays. Excision of basal cell epithelioma is of undoubted value if one can sacrifice sufficient healthy tissues surrounding the lesion, but as the larger percentage of basal cell epitheliomata occur on the face, where sacrifice of considerable tissue is not warranted or would cause poor cosmetic results, as on the eyelid or ala of the nose, one must give the preference to the two preceding measures. Various kinds of arsenical pastes or caustic pastes are of benefit at times in the

treatment of this type of lesion but they are more painful and less desirable so far as the cosmetic result is concerned. The use of carbon dioxide snow has the same draw-back as pastes in the treatment of this type of lesion.

In squamous cell epithelioma of the skin, the same relative value of methods of treatment for the primary lesion exists, but one must keep in mind that the squamous cell or pearl forming variety of epithelioma requires two to three times as much radiation as the ordinary basal cell type. Here again the preference as to radiation, endothermy or surgery is given to the method with which one has had most experience, the preference being for radiation, in some cases diathermy, and in far advanced epithelioma occurring in extremities such as the hands, fingers or legs, surgery may be preferable. One must always keep in mind that no matter which method is pursued, this variety of tumor is prone to metastasize and the regional lymphnodes should be thoroughly radiated even though no metastases are present.

A common site for this variety of epithelioma is on the lower lip at the mucocutaneous junction, where we encounter two varieties, the proliferated type and the infiltrating type. The permanent results following irradiation and surgery, so far as the local lesion is concerned, are equal in our experience, with the exception that better cosmetic results are obtained from radiation treatment. Cancer of the lip in the early stages, can be treated satisfactorily by excision or by means of radiation, radiation giving the better cosmetic result locally. When there are definite metastases in the submaxillary or submental regions, surgery alone does not suffice. It is extremely necessary that the metastases be treated by radiation, implantation alone or combined with external x-radiation. The results from radiation alone compare with the best surgical statistics if the disease is local. If lymphnodes are involved one can expect only about 34 per cent clinical healing by means of radiation and implantation. Cases treated by surgery alone I believe are less satisfactory.

Cancer of the oral cavity and its contents, namely the tongue, floor of mouth, gums and inner cheeks, is without doubt treated best by irradiation, the implantation of radium emanation filtered through gold, keeping in mind always that x-radiation is to be applied over the lymph-bearing areas. Epithelioma of the tonsil and pillars is without doubt handled best by implantation with radium. The round cell sarcoma occurring in the tonsil is preferably treated by means of high voltage X-rays or large radium packs applied externally, as this type of tumor is very susceptible to radiation.

The most common variety of malignant disease of the antrum is carcinoma, which if early is best treated by radium implantation, or radium

tubes inserted into the antrum through the roof of the mouth. This is productive of healing in about 25 per cent of the cases. When further advanced, involving the cheek and with metastases in the neck, the results have only been palliative.

Spindle cell sarcoma and myxo-sarcoma, which occasionally occur in the antrum, have yielded practically no curative results by any known method of treatment.

Giant cell tumor involving the antrum is best treated by surgery combined with radium. This has yielded very good results in a few cases treated.

Cancer of the oesophagus, in early cases, has been treated surgically by resection with, I believe, two cases that have lived. Radiation up to the present time has offered nothing but palliation, but in this locality we are confronted with two problems, namely, the cancerous disease itself, and as a result of this the mechanics which lead to starvation, where without doubt gastrostomy should be performed early.

Carcinoma of the stomach is best treated by surgery, performing resection where the lesion is favorably located, if at the lower end of the stomach, pyloric region, or by the combined method of gastroenterostomy where there is obstruction at the pylorus, and the implantation of emanation into the primary growth. I have successfully done this in two cases, the patients living  $2\frac{1}{2}$  and 2 years respectively, it is of course unnecessary to remind you that this procedure is only applicable when there are no metastases in the liver at the time of operation.

Cancer of the cecum and colon is best treated when operable, by resection because of the stenosis and obstruction which is an accompanying part of the malignant disease. Where these lesions are inoperable, on account of invasion of the surrounding tissue, palliation can be offered by means of high voltage X-ray, or radium packs. For lesions located in the sigmoid, the two stage operation of Mikulicz is productive of very good results.

Cancer of the rectum is exceedingly discouraging from the standpoint of surgery and all other forms of treatment. One cannot deny that in selected cases in which the tumor is movable, and occurring in the lower two to three inches of the rectum, it can be removed surgically through the anal canal as described by E. R. McGuire, and others. By far the larger percentage of cancer of the rectum is inoperable on account of fixation and involvement of contiguous tissues, which renders surgery inadvisable except in a palliative way, in the performing of a colostomy. These lesions when local and low down are best treated by the implantation of gold seeds of emanation, and when higher up tandem tubes of radium emanation in the lumen of the stricture, supplemented with high voltage X-rays

from the outside, the question of colostomy being left until the mechanical obstruction is almost complete. This is contrary to the opinion of many, who think that on account of the continued irritation due to the stools passing over this ulcerating area and thus causing irritation, colostomy should be done to avoid this irritation. It is my conclusion reached after the observation of many patients who have had colostomy performed with this idea in mind, that after this operation they had two sources of annoyance, the discharge from the rectum as well as the care of the colostomy opening itself. One can expect about eight to nine per cent clinical healing from this form of treatment.

**Cancer of the female genitals.** The most frequent type of cancer involving the female genitals is epithelioma or squamous cell carcinoma involving the cervix. There is no doubt that the treatment of choice in this lesion, which is concurred in by all gynecologists of note, is radiation. The results of radiation treatment, as to healing, are in direct proportion to the length of time the disease has existed. In order to grasp what has been accomplished in this type of cancer, it is necessary to divide it into groups according to the anatomical involvement. (Early cases confined to the cervix are designated as Group I, where there is obliteration of one or the other fornix with invasion of the mucous membrane of the vagina Group II, beginning invasion of the broad ligament areas Group III, and complete fixation of the uterus and possibly involvement of the bladder and rectal walls Group IV.) By combined treatment with radium inserted into the cervical canal and supplemented with high voltage X-rays externally, one can expect in the early cases results which far surpass surgical results. This is indicated by the fact that we have had twenty-two out of twenty-three cases which have been healed from periods of 2 to 7 years, one case having recurred and died 2½ years after treatment. In the Group II cases about 50 per cent have remained well for periods up to 5 years, in Group III about 24 per cent. In Group IV palliations have lasted as long as 3 to 5 years.

Another type of lesion that occurs in the cervical canal, is adenocarcinoma. This type seems to be much more malignant and the results of treatment are not as good as with epithelioma. While this lesion is less frequent we have observed sixteen cases. In the early ones, in which the lesion was confined to the cervical canal we have obtained about 57 per cent clinical healing. In the far advanced cases, treatment has been the means of prolonging life.

Carcinoma of the fundus, if early and confined to the uterus, is considered a surgical disease and results are extremely gratifying, various authors claiming 75 per cent of healing over periods of 5 years. Many times, however, there are

contraindications to operation, such as old age, myocardial disease, diabetes, and refusal on the part of the patient to submit to operation. We have collected records of fifty-six cases treated by radiation alone, with the gratifying result that 72 per cent remained well and free from the disease 2 to 5 years. The far advanced and inoperable carcinoma of the fundus of the uterus has been treated by radiation with only palliative results from 1 to 3 years. Recurrences occurring locally in the vault of the vagina and broad ligament areas treated by combined method of radium and X-ray have resulted in healing 32 per cent from 2 to 5 years.

Cancer of the ovary is best treated when local, by the combined method with surgery, the removal of all the pelvic organs, or when this is not possible, the removal of as much of the diseased tissue as possible, this to be followed by external radiation. While the clinical healings or cures in this type of malignant disease are few, the average length of life has been increased up to periods of 5 to 6 years.

Cancer of the vagina is a hopeless disease from the standpoint of surgery, because of the difficulties of mechanical removal of such growths, as well as the fact that the majority of cases are advanced locally by continuity of tissue so that the bladder and rectal walls are involved. Our only means of attack at the present time is by thorough radiation. This is naturally limited because of the mechanical difficulties and the liability of the production of fistula, either bladder or rectal. In the early cases, we have succeeded by radiation in effecting a healing in half of them from 2 to 4 years and in the advanced cases two out of twenty-one have been well 3 to 5 years.

Malignancy of the female external genitals, clitoris and vulva, is exceedingly painful and difficult in effecting a healing. After an experience with thirty-one cases of cancer of the clitoris and vulva we have come to the conclusion that the best way of handling these cases is by the combined method of radium implantation locally and at times into the metastatic growths in the groins, with electro coagulation and destruction of the whole vulva and clitoris. This has been the means of rendering these patients much more comfortable and effecting clinical healing for period of 1 to 3 years. Cancer of the external genitals is prone to recur locally and the metastases to become intractable.

**Male genitals.** I am of the belief, after careful study of forty-eight cases of cancer of the penis, that in selected cases where the growth is papillary and local, it can be dealt with effectually and healed by pure radiation, using unfiltered X-rays and radium implantations. Because of the mechanical difficulties arising, it is often wiser to resort to radical operation with dissection of both groins, and the transplantation of the urethra in-

to the perineum, this to be followed by external radiation. Authorities differ as to the necessity of castration at the time of radical operation. Some authorities do not believe it necessary or desirable. However we have had one case in which there was found a metastatic deposit in the testicle. True it is that surgery alone rarely, if ever, cures cancer of the penis in cases where there are definite metastases in the lymph nodes of the groins. By implantation of radium emanation into the metastatic nodules we have seen the disease apparently healed,  $3\frac{1}{2}$  years after treatment.

Early cancer of the breast, as a rule, is best treated by combination or radical surgery to be followed by high voltage X-rays, with some exceptions where implantation of radium, and radium packs have proven of absolute benefit in a curative way. Theoretically, it would be of material benefit to subject all cases to pre-operative radiation by means of high voltage X-rays, were it not for the fact that frequently there is experienced great difficulty in the healing of wounds. We have been carrying on work to establish whether it is possible to radiate, in divided doses, beginning before operation and carrying it through the time of wound healing and still expect an improvement in the results.

Our statistics show definitely that results in operable cases are best obtained by radical operation followed with radiation, although in some instances, radiation alone has proven of value in a curative way. The palliations obtained by radiation in the hopeless, inoperable cases of breast cancer have been instrumental in making the remaining days of the patient more comfortable.

Sarcoma, of which there are many varieties histologically as well as clinically, may be, for the sake of convenience, divided into several large groups. Lymphosarcoma should never be dealt with surgically except for the establishment of an absolute diagnosis as to the type of tumor with which we are dealing. This tumor is extremely susceptible to radiation, frequently melting away in a remarkably short period of time. One is obliged to remember that lymphosarcoma is a disease of the lymph tissue throughout the body and therefore crops out in various places. If local the disease is curable, patients having lived without any evidence of recurrence up to 8 years.

Spindle cell sarcoma of the fascia plane is

best treated by removal when possible, followed by radiation.

Giant cell tumor occurring in the bone and in tendon sheaths may be dealt with surgically by enucleation or curetting out and at times resecting portions of bone or joints and in some cases it has been successfully treated by radiation alone.

Myxosarcoma is primarily a surgical disease, which necessitates extremely radical procedures, and where favorably located on limbs or extremities, amputation is almost the only means of effecting a cure. This tumor recurs locally and leads to death by impairment of function. It is very resistant to any form of radiation, although in two cases we were able to render palliation by radiation up to 3 years.

Osteogenetic sarcoma is an extremely fatal disease, because of its early metastases which occur, especially into the lungs. It should be dealt with by means of radiation as a palliative measure and at times surgically, for the alleviation of pain and ulcerating lesions. The prognosis is invariably bad. I know of no case that has remained well 3 years from any form of treatment.

There is at present no means of curing disseminated cancer. Radiation, whether by radium or X-ray, is limited in so far as one can thoroughly treat a given area in which there is cancerous tissue. Surgery is useless except in a palliative way as for the relief of pain or hygienic reasons. From time to time numerous investigators have suggested medicaments of various types in the treatment of wide-spread cancer. Among these may be mentioned that of Blair Bell who used colloidal lead and reported good results in a curative way on cancer patients. After Bell's original article in 1923 we treated a few cases with colloidal lead but abandoned it as there were no clinical results noted. Again in 1926 we undertook an investigation in nineteen cases in which the lead treatment was carried out as near as possible according to Bell's methods. All these cases have since died of the disease with the exception of one, who is now moribund. The severe anemias produced by the use of colloidal lead and lack of improvement clinically in the local lesions, was cause enough for the rejection of this method of treatment as being ineffectual. Sodium oleate and arsenical medications seem to be of benefit in a general way. Numerous physicians have proposed serum and specific antitoxins as well as colloidal preparations like gold, all of which have proven of little or no value.

## PREVENTION AND DIAGNOSIS OF CANCER

By ISAAC LEVIN, M D, NEW YORK, N Y

THE methods of prevention of a disease must of necessity vary with the variations of its etiology. In infectious diseases, for instance, prevention means isolation of the patient and the prevention of the spread of the microorganism into the community. In cardiovascular diseases prevention may mean the regulation of the mode of life. In inheritable diseases it may mean control of mating, and so on.

It would seem *a priori* that in cancer the etiology of which is not clear today, prevention is entirely impossible. In reality, however, the pathological, experimental and clinical studies of the last thirty years have elucidated many phases in the etiology and particularly in the pathogenesis of cancer. As a result, as will be shown later, the term *prevention of cancer* has a very important practical meaning and will produce ever better practical results as cancer research both experimental and clinical, progresses.

*Pathogenesis of Cancer*—The general impression of the public and the assumption by some members of the medical profession that cancer from its very inception is either an infectious, systemic or a nutritional disease is contrary to all evidence in scientific medicine.

Clinically the beginning of cancer manifests itself always by the formation of a local tumor without any accompanying disturbance in the organism. Indeed, the lack of general symptoms is one of the main reasons for the late recognition of the disease. Throughout the whole course of cancer its malignancy is most generally due to local destruction of some vital organ by a primary or a secondary metastatic tumor. Unlike any known systemic or parasitic disease the main characteristic of which is regression and inhibition of cellular growth and function, cancer is always characterized by new growth, progressive multiplication of cells and increased cellular metabolism. Massive malignant tumors may absorb most of the nutrition taken in by the individual and throw into circulation the products of its own cellular functions which are toxic to the organism, and so create *emaciation, anemia and cachexia*. All these manifestations, however, are secondary and of far less importance in malignancy than the local destruction of vital organs.

The development of a malignant tumor is undoubtedly due to two factors: (1) the presence of a group of peculiarly changed cells and (2) the condition in the tissues or organ surrounding this group of cells which is favorable to the multiplication and the development of these changed (cancer) cells. Ribbert who for years maintained that only the second factor is needed for

the formation of cancer and that otherwise every normal organ or tissue cell is potentially a cancer cell, in his latest publication also admits the existence of the two factors described above. He maintains now that the changes in the subepithelial connective tissue, which formerly served as the basis for his theory of the formation of cancer, appear frequently without a subsequent development of cancer. According to his latest conception, therefore, only certain specific kinds of subepithelial inflammatory processes may induce the formation of cancer. This specific *precancerous inflammation* of connective tissue is caused by products of the degenerative changes in the same epithelial cells, which subsequently lose their differentiation and acquire the proliferating power. In other words, they become *cancer cells*.

There has been gathered in the last quarter of a century a mass of clinical and experimental data which supports the view that a group of potential cancer cells will not develop a cancer unless there exists somewhere in the organism an area which through disease, abnormality or constant irritation becomes susceptible to formation of cancer. In other words, enters into a *precancerous state*.

### PRECANCEROUS CONDITIONS

*Experimental Studies of Precancerous Conditions*—In 1913 Fibiger reported on a series of experiments which consisted in feeding rats with cockroaches infected with a nematode (threadworm). These rats developed in the stomach inflammatory conditions, papillomata and in a certain number of cases a true carcinoma with formation of metastases. This carcinoma he succeeded in inoculating into normal rats.

About the same time Yamagiwa and Ichikawa, two Japanese investigators, reported that they succeeded in artificially producing malignant epitheliomata of the skin by painting the skin of the animals—rabbits and rats—with coal tar and its derivatives. Since then a great deal of similar work is being done all over the world.

Two factors stand out prominently in all these experiments: (1) That the irritation must be continued for a long time. Eight months of treatment of a rat corresponds to about twenty-five years of treatment in a human, since the life cycle of a rat is only two years. (2) Only a small fraction of the number of animals experimented upon (10 per cent to 25 per cent) develop true malignant tumors, while the rest of the animals show at best only precancerous conditions. The significance of these two facts will be discussed later.

In the ultimate analysis the results consist in the following: The parasitic or chemical irri-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, May 12, 1927.

tants produce a precancerous condition or in other words a favorable soil on which either an inoculable or a spontaneous malignant tumor develops. In this respect the results are analogous to an artificial production of a precancerous state which the writer reported in 1912. The research consisted in inoculation of various types of carcinoma and sarcoma of the white rat into different organs of normal animals. A "Flexner-Jobling" type of carcinoma of the white rat grows readily when inoculated subcutaneously or in any other organ, but does not grow when inoculated in the testicle.

In a series of animals the writer treated the testicles before the inoculation of the tumor with injection of a solution of Scharlach-R in Oil or with a 40% mixture of sulfuric ether in water. As a result of this treatment there was noted an injury of the parenchymatous tissues of the organ and formation of inflammatory connective tissue. The subsequent inoculation of the Flexner-Jobling carcinoma in such testicles was successful. In these experiments, like in the experiments with parasites or the coal tar products, the soil was made favorable for the development of cancer, a precancerous condition was created.

*Clinical Studies of Precancerous Conditions*—There has accumulated, of recent years, much clinical evidence of a direct relationship between chronic irritations continued for years and the formation of cancer. East Indians in Kashmir who use *Kangri coal stoves*, develop epithelioma of the skin of the abdomen on the basis of a dermatitis produced by the heat of the stove. The Eastern women, who constantly chew *betel-nut*, develop epitheliomata of the cheek in the area in which the betel-nut was kept. Dr. A. Scott made an exhaustive study of the occupational dermatoses of the paraffin workers of the Scottish *shale oil industry*. A certain number of the workers develop epithelioma following these occupational dermatoses. Workers in anilin dye factories develop cystitis and subsequently carcinoma of the bladder. Carcinoma of the bladder infected with *bilharzia*, *Paget's disease of the nipple*, epithelioma arising on the basis of an *X-Ray dermatosis* are other instances of the same kind. This clinical evidence leaves no doubt that continued chronic irritation acts as a precancerous condition and prepares a favorable soil for the development of cancer. A very interesting case came to New York City Cancer Institute recently in which an epithelioma developed on the basis of a tubercular skin ulcer. The case was reported elsewhere. The writer has shown in his clinical investigations that Hodgkin's disease begins as an infectious granuloma and then subsequently develops into a true lymphosarcoma. In some instances both conditions may be found in the same microscopic section.

The relationship between the formation of cancer of the *lip, tongue, mucous membrane of the mouth* and precancerous inflammatory conditions due to smoking, bad teeth, faulty dentures, plates or bridges, tuberculous or syphilitic conditions is also fairly evident. It is somewhat more difficult to trace this direct relationship in the development of other types of cancer, though the precancerous inflammatory conditions and cancer are noticed side by side. Cancer of the breast frequently can be shown to have developed on the basis of chronic mastitis. Lacerations and erosions of the cervix are followed by cervical carcinoma. The writer has observed several instances in which carcinoma developed on the wall of a tubercular cavity in the lung. Many more instances may be cited in which such correlation is present.

The relationship between carcinoma of the stomach and a gastric ulcer is still a matter of dispute. Pathologists maintain that there is no relationship between the two conditions while clinicians of wide experience claim that there is no doubt of the existence of such relationship. One must take into consideration the fact that like in all precancerous conditions cancer develops only in a small percentage of cases of gastric ulcer. Furthermore, the clinical history of the case may show the pre-existence of an ulcer and at an operation an early cancer may be found. But by the time the case comes to autopsy the advanced carcinoma may have destroyed all evidence of a former ulcer.

The same two factors which were shown to be of importance for the chronic irritation produced artificially in animals, namely, that the irritations must continue for a long period of time, and that only in small percentage of cases does cancer actually develop, are true in precancerous conditions in the human. The irritations must continue uninterruptedly for years and only in a small percentage of cases does cancer actually develop.

*Precancerous Conditions and the Parasitic Theory of Cancer*—The search for a specific microorganism as the etiological factor in cancer began forty years ago immediately upon the discovery of the parasitic origin of infectious diseases. An amazing amount of work was done on the subject. In the majority of instances the specific organism upon further investigation proved to be an innocent saprophyte. It is impossible to attempt here to analyze all these investigations. One instance may serve to illustrate the point. Scheuerlen reported in 1887 that he obtained in pure culture grown on potato the specific microorganism of cancer. It has taken the work of many investigators for several years to show that the bacillus was an ordinary potato bacillus—a harmless saprophyte. Every known type of plant or animal parasite was considered specific for cancer. Occasionally

commercialism obscured the problem. Several years ago Otto Schmidt claimed not only to have discovered the specific cancer agent, the so-called *Mucor racemosus*, but to have also obtained a specific curative agent called *aristem*. The whole subject was thoroughly discredited by scientists at the time. However, a few weeks ago a German sales agent approached the writer with a request to try a new edition of the remedy which had just arrived from Germany under the name of *novaristem*.

All the former conceptions of the parasitic origin of cancer were purely hypothetical and the opinion of the majority of the scientific investigators including Virchow and his school of pathologists, was against it. With the advent of experimental cancer research, however, the question of the parasitic theory became again the order of the day.

In 1907 Dr. E. F. Smith showed that the disease of plants called Crown-gall—tumor-like in nature—could be reproduced artificially by an inoculation of a normal plant with a pure culture of a bacillus which he called *Bacterium tumefaciens*. Smith maintained that Crown-gall is a true plant cancer. In his estimation this tumor is practically identical biologically with animal and human cancer. Since Crown-gall is caused by the action of the bacterium *tumefaciens*, he concluded in one of his recent articles that "to a biologist the conclusion is almost irresistible that human cancer must be due to a parasite and that one parasite may well be the cause of the most diverse forms, as we have seen to be the case in plants." This deduction is so sweeping in character, so far reaching in its generalization, and the results of Dr. Smith's work have become so widely known and quoted by the medical profession, that it has seemed to the writer to be desirable to renew his investigations and to analyze the material from the viewpoint of animal pathology and to attempt to determine the true analogy between the Crown-gall and animal cancer. The investigation was done in collaboration with a botanist, M. Levine.

The results obtained may be briefly summarized as follows. Crown-gall is undoubtedly a neoplastic disease and the pathogenesis of the condition consists in an abnormal proliferation of a group of cells.

In order to formulate clearly, however, the position which the Crown-gall occupies among the neoplastic diseases, one must take into consideration the fact that the Crown-gall is usually a benign condition and only rarely does it act in a manner analogous to a malignant tumor in an animal.

The malignant type of Crown-gall is undoubtedly quite analogous to animal cancer. This malignant transformation occurs, however, rarely, and is not related to the function of bacterium *tumefaciens*.

The possibility of omnipresence of a specific microorganism causing the formation of all types of cancer cannot be denied offhand. However, the behavior of such hypothetical organism would have to be different from that of any parasite known to date. All pathogenic microorganisms investigated thus far produce a destructive degenerative effect on the cells of the invaded tissues. This effect may be accompanied by reactive neoplasia of the lymphoid tissue. It is conceivable that such a purposeful reactive neoplasia may gradually change into malignant neoplasia of the local connective tissue when the soil of the host is favorable. The pathogenesis of sarcomata, particularly lymphosarcoma, Rous' chicken sarcoma, as well as the plant tumors, as was shown above, may be closely related to the pre-existing reactive neoplasia caused by a parasite. In other words, it is difficult to prove that in connective tissue cancers the secondary tumors are metastatic and are not created anew in the distant regions through the action of an invisible parasite on the connective tissues of the new location. A metastatic adenocarcinoma of the rectum in the brain from a primary in the rectum, however, cannot be conceivably created from any of the cells of the latter organ.

The action of a hypothetical cancer microorganism can be conceived only in one of the following two ways. Either the organism acts on the first group of organ cells, changes them into cancer cells and then ceases its function. In this case the action of the parasite would be subordinate to the cellular function and would not differ from a non-specific chemical irritant. The proliferative power of cancer cell itself would be the true cause of cancer. Else the constant presence and action of the parasite is needed for the formation of the primary as well as the secondary malignant tumors. Such a parasite would have to live in symbiosis with the cancer cell, divide simultaneously with the latter and migrate together throughout the organism of the host, in a word, must submerge its life and function with the life of the cancer cell.

*Precancerous Conditions and Inheritance in Cancer*—An analysis of all the available data of the causation of cancer indicates that the formation of a malignant tumor is the resultant of three factors. (1) The innate power of every normal cell to proliferate. This fact, that any normal cell relieved of the restraint of the rest of the organ begins to proliferate has been conclusively proven by the successful cultivation of normal as well as cancer cells *in vitro*. (2) An irritant which initiates the proliferation of cells for the purposes of protection and repair. (3) Lack or weakness of those inhibiting powers of an adult organism which keep in check all its normal tissue cells against purposeless malignant proliferation.

While the second factor is extrinsic in its nature, the first and third factors are inherent characteristics of all living organisms. It is plausible to suppose a priori, therefore, that these latter factors in causation of cancer may be characteristics transmitted by inheritance to subsequent generations.

The problem of inheritance in cancer has been occupying the minds of investigators for a long time. The results were rather unsatisfactory. With the advent of the modern science of genetics, which is based on the fundamental laws of inheritance discovered by Mendel in 1865, the subject of inheritance of cancer was taken up anew.

The writer has shown in 1910, in a series of experiments, that the offspring of rats immune against the inoculation of a tumor is partly immune and partly susceptible to the inoculation. The ratio between the number of resistant and susceptible animals seemed to correspond with the Mendelian laws and also seemed to indicate that the inherited power of resistance is a dominant unit character in accordance with the terminology of Mendelian genetics. Similar conclusions were arrived at by Maud Sly in her studies of inheritance of spontaneous tumors of mice. Th. H. Morgan and his pupils have discovered a malignant tumor of the fruit fly (*Drosophila melanogaster*) which is transferred by inheritance in conformity with Mendelian laws. The writer made a study of the influence of heredity in human cancer by the aid of an analysis of the collected data in accordance with the Mendelian laws of eugenics. A number of families were studied for several generations back. The analysis of the material shows that the incidence of cancer in these families is not greater numerically than would be found among the population of the community as a whole.

The further conclusion may be thus drawn from the analysis of the results obtained that *resistance to cancer is a dominant character whose absence creates the susceptibility to cancer*.

The most important result of the investigation thus far consists in the fact that it shows the importance of the presence of an inherited resistance to cancer growth. It may be of the greatest benefit for the future study of the subject of cancer to bear in mind not the fact that out of ten persons who reach the cancer age one suffers from the disease, but that nine out of ten remain immune.

It is very significant in this connection that an analysis of all the material experimental as well as clinical, obtained in the study of the relation of chemical or parasitic irritants on the formation of cancer, show the same results. Namely, of the whole number of animals used or the clinical cases investigated, only a comparatively small percentage develops cancers. This successful fraction generally ranges somewhere be-

tween 10% and 25%. This is rather close to the main fundamental Mendelian law that in the second generation there appear 75% with dominant unit characters and 25% recessive.

The sum total of our knowledge of the causation of cancer to date make the following conceptions to be the most plausible: (1) Attempts at formation of cancer in any organism is frequent but the greatest number of people (not less than 75%) have an inherited capacity to resist the formation of cancer. (2) The human society is so inbred that every family has a certain number of members in one generation or another with an inherited susceptibility and further intermarriage cannot alter the situation. Consequently, in reality inheritance does not increase the chances of an individual to develop cancer. (3) Without an additional local irritation of some kind, cancer may not develop even in a susceptible individual.

#### THE MEANING OF PREVENTION IN CANCER

Cancer is a disease of advanced age. An irritation due to occupation or improper mode of life must continue, as was indicated above, for a number of years before a cancer will develop in a susceptible individual. It is impossible to foretell who are the susceptible individuals in a group of a hundred men who are engaged in X-ray work or in shale oil industry or neglect the rules of oral hygiene. But were all the hundred men properly protected in their industries or in their modes of life, the susceptible individuals would not contract this special type of cancer and thus may be enabled to pass their normal span of life without developing any type of malignancy.

It is self evident that prevention in cancer means to prevent by the aid of protective or correcting measures the development of precancerous conditions and to correct and cure these conditions before they have developed into true cancers.

In certain very important types of cancer, namely, those of the gastro-intestinal tract, the breast, the uterus and the genito-urinary organs, the true nature of the precancerous conditions is not certain, and the matter requires further investigation. This is a subject for *clinical cancer research* and must be pursued on large clinical material very painstakingly and thoroughly treated.

*Prevention of Cancer* means recognition of precancerous conditions and the resulting early stages of cancer and the prompt and efficient treatment of these conditions. Consequently, *prevention of cancer means early diagnosis of cancer*.

#### CANCER DIAGNOSIS

Many attempts were made to apply the serological methods of diagnosis which are of such importance in parasitic diseases, to the diagnosis

of cancer, but with uniformly negative results. Of greatest promise seemed to be for a time the so-called Abderhalden test. The writer in co-operation with Van Slyke has definitely proven the method to be of no value.

**Pathological Diagnosis**—At the beginning of the pathological study of cancer the fine morphological differences, as observed under the microscope, did not seem to have any bearings on the clinical condition, had only an academic interest, so to speak, and seemed to be of much less intrinsic value than the descriptive botanical classification of plants, for instance. However, the clinical study of cancer kept pace with the progress of clinical medicine, and with the development of the more and more refined methods of diagnosis of the diseases of the various organs and systems of the organism. It was soon noticed that in order to obtain a correct estimation of the clinical course of a malignant tumor and of the consequent method of treatment and prognosis both the morphological structure of the tumor and the place of its derivation has to be considered. For instance, adenocarcinoma of the cervix has a different clinical course, requires a different method of treatment and gives a different prognosis than a similar adenocarcinoma of the body of the uterus.

W S Lindsay has further demonstrated very recently that the carcinoma of the body of the uterus itself has to be divided into two groups, one, adenoma malignum which is of low grade malignancy and is very readily influenced by radiotherapy without any surgical intervention, and adenocarcinoma of the body of the uterus which is a highly malignant type of disease.

On the other hand, two tumors of the same organ but with a different microscopical structure, carcinoma and lymphosarcoma of the tonsil, for instance, have an entirely different clinical course and present a different prognosis. At the same time on clinical analysis without the aid of the microscope these two conditions frequently cannot be differentiated from each other. The investigations of A C Broders seem to indicate that grades of malignancy and consequent therapeutic results may be differentiated through the study of morphological differences even in the same type of a malignant tumor.

Of particular value is the pathological research in connection with the relationship between the morphological structure of malignant tumors and the therapeutic results obtained. It has been shown that radium and the X-rays act differently not only on tumor tissues as compared with normal tissue but also give better results on certain morphological types of malignant tumor tissue. The same must be true as regards the ultimate results of surgical therapy.

**Influence of Early Diagnosis on Therapeutic Results**—The perusal of therapeutic results obtained in cancer by the aid of surgery, radium

and X-rays shows a situation apparently paradoxical. On the one hand, in selected cases not less than 50 per cent of the cases operated upon may be cured by surgery alone. Radium and the X-rays produce such striking results in even hopeless inoperable cases that with a proper co-ordination of surgery, radium and X-ray therapy undoubtedly a larger percentage than 50 may be cured of the selected group of cases. On the other hand, only a small percentage of all the cancer patients of a community is cured of cancer with all the therapeutic methods at our command. What is the reason? The patients are coming too late for treatment. The chart shown here gives the difference between the surgical results in cases that come for treatment early as compared with those that come for treatment late.

	% of the total No of Cancer Patients	% of possi- ble S'g'e'l Cures	% Cured of total No of Cancer Patients	% Act'ly Cured Sur- gically	% Act'ly Cured of Total No. Can. Pts.
Intraoral Cancer	4	75	3	20	08
Stomach	30	25	75	3	09
Rectum	10	30	3	9	09
Uterus	15	50	75	10	15
Breast	10	70	7	20	2
Skin	3	100	3	—	3
	72	—	31	—	91

R Peterson in a paper on the radical abdominal operation for cancer of the cervix reports that 59 per cent of all the cases that he operated were permanently cured. However, of 380 patients suffering from cancer of the cervix who came to him for treatment only 60 or about 15 per cent were found to be operable, all the others, or 85 per cent came too late for treatment. Dr Gibson, reporting on 110 cancer patients cared for at the New York Hospital from February 1913 shows again that 84.5 per cent entered the hospital in a late hopeless condition. Fully half of these late cases were treated by physicians for months without a recognition of the true nature of the disease. In the experience of the writer, both in the hospital and private work, nearly 75 per cent of the cancer patients were treated by physicians for a longer or shorter period of time without a diagnosis of malignancy. The fault does not lie in the lack of therapeutic measures, of a "cancer cure." Treatment that succeeds in over half of a selected group of cases ought to be able to take care of most cases of cancer. Nor is there any weakness in diagnostic methods. With the aid of *pathological and chemical laboratories, roentgenography, illuminating methods* (laryngoscopy, oesophagoscopy, proctoscopy, cystoscopy, bronchoscopy) and a *thorough clinical investigation*, very few cases of early cancer should escape detection.

#### CANCER DIAGNOSIS AND PERIODIC HEALTH EXAMINATION

The real difficulty in cancer diagnosis lies in the fact that at the beginning and the early de-

velopment of the disease it is not accompanied by symptoms sufficiently characteristic to cause the patient to consult a physician. What makes the situation graver still is the fact that when the physician is already consulted the symptoms are so vague that on their basis a tentative diagnosis of malignancy cannot be made. The physician whom the patient consults first, the family physician, is a general practitioner. The tendency of the latter is usually to use therapeutic measures and relieve the urgent symptoms, the discomfort of the patients, rather than to make a thorough diagnostic analysis of the case. The result is a temporary relief of the symptoms and a continued unabated development of the malignant growth. A woman may be relieved temporarily of her uterine bleeding and offensive vaginal discharge by appropriate medication, though the cause of both is a uterine malignant growth. Symptoms of dyspepsia may be relieved temporarily though the cause of it may be an early cancer of the stomach, and so on.

It is of the utmost importance for the practitioner in medicine to realize that a complete and thorough examination of the whole organism of the patient is the prerequisite for the detection of the early stages of cancer. Furthermore, real progress in the early diagnosis of cancer will only take place when the general public becomes educated to the necessity of periodic health examinations. This education can be done efficiently only by each practitioner in his own lay circle.

#### CANCER DIAGNOSIS AND GROUP PRACTICE OF MEDICINE

Periodic health examination means an analysis of every organ and system of the organism of the patient. This is particularly important for the detection of early malignancy. The writer had occasion to examine many patients whose chief complaints gave suspicion of malignancy in a certain organ. The findings in this organ were negative, but an entirely different organ showed early malignancy though there were no symptoms indicating it.

It is impossible for one individual physician to master all specialties, therefore, periodic health examinations will become a success only when even in small communities the physicians will group together, each one become proficient in one specialty though not relinquishing the general practice of medicine.

#### THE NEED OF CANCER CENTERS

The medical profession and particularly the surgical specialists maintain that the diagnosis and therapy of cancer do not constitute a specialty and that a well equipped general hospital is fully capable of taking care of cancer patients. This in spite of the fact that specialization in medicine is drawn so fine today that,

for instance, we do not only have laryngologists, but tonsilologists and special tonsil hospitals. It is impossible to conceive that cancer, a chapter in medicine which presents the most complex and difficult problems, as regards research, diagnosis and therapy, is not a specialty. While admitting that an individual surgical clinician of experience may be able to take care of any cancer patient in a correct manner, there are many reasons which make the organization of special Cancer Centers or Hospitals indispensable. Such Cancer Centers must not only take care of cancer research but also must actively care for and treat cancer patients. The following are some of the reasons which make the establishment of Cancer Centers the most important step in the solution of the Cancer Problem.

1 At present there is no question that the great majority of lay people fear the knife and hope that their particular cancer—and many of the cancer patients suspect if they do not actually know that they suffer from the disease—can be cured by another remedy than the surgical intervention.

In the course of many years of clinical work at the Montefiore Hospital and particularly at the New York City Cancer Institute, which is known to be a clinic and hospital for cancer patients only, the writer has made over and over again the following observation. A cancer patient who refused to be operated upon at the advice of a general surgeon and enters the New York City Cancer Institute with the hope of finding another remedy, readily undergoes the operation when so advised at the Institute. On the other hand, if recognized cancer institutions were non-existent, this would play into the hands of commercial establishments like the Koch Cancer Foundation, and many similar fake organizations who actually advertise their antitoxins, serums or what not, and claim to cure all cases of cancer. They bear pseudo scientific names, claim to have special scientific departments, have physicians' names on their literature which simulates in form real medical literature, and use all the slogans of scientific institutions. If scientific medicine refuses to maintain cancer hospitals and cancer institutes then cancer patients will be thrown to the mercy of these quack institutes. That is undoubtedly a very important reason for the need of a cancer center.

2 The other reason for having Cancer Centers is the educational influence which their mere existence would exert on the general public. The fact that a number of scientific institutions are organized for the treatment of cancer, will impress the public as proof that cancer cannot be a hopeless condition since otherwise there would exist only homes for incurables to which cancer patients would be sent to die.

3 The third and most important function of a Cancer Center is the following. A few sur-

geons of experience may know all the phases of Clinical Cancer but the profession at large recognizes only the late hopeless stage of the disease and misses the early hopeful stage with a resultant pessimistic attitude to the whole problem. Unfortunately this is true even when it concerns the physicians' own families. A young surgeon who obtains his training in a fully equipped cancer hospital and clinic has an opportunity to see side by side all types of cancer patients. Clinically, I divide all cancer patients in the following three groups. Class A patients are either in a pre-cancerous state or in so early a stage of the disease that it takes little effort to control it. The class B patients are the so-called operable or border-line cases for which there is a good chance of arresting the disease. Finally,

the class C patients are hopeless cases, who cannot possibly be taken care of in an acute surgical hospital because they require too long a period of hospitalization. When the young doctor becomes accustomed to seeing all the three types of cancer patients in the same institution he will be able in future practice to visualize in his mind a picture of Class C when he sees a patient in Class A, and therefore he will take seriously every Class A patient and will not wait with therapy until the patient reaches the stage C. At the New York City Cancer Institute, I consider this training and education, not only of the young resident staff, but of all physicians who visit the Institute or refer their patients to it, our most important function.

## POPULAR EDUCATION AS A FACTOR IN THE CANCER PROBLEM\*

By JOHN M SWAN, M D, ROCHESTER, N Y

Chairman of the New York State Committee of the American Society for the Control of Cancer

AT the International Conference on Cancer Control held at Lake Mohonk in September, 1926, the students of the cancer problem, who there discussed ways and means, agreed to a statement of facts and opinions on the methods to be followed. Among these statements occur the following: "3 The control of cancer, as far as this subject can be understood at the present time, depends upon the employment of measures of personal hygiene and certain preventive and curative measures, the success of which depends upon the intelligent cooperation of the patient and physician.

"4 Persons who have cancer must apply to competent physicians at a sufficiently early stage in the disease, in order to have a fair chance of cure. This applies to all forms of cancer. In some forms early treatment affords the only possibility of cure.

"7 The public must be taught the earliest danger signals of cancer which can be recognized by persons without a special knowledge of the subject and induced to seek competent medical attention when any of these indications are believed to be present.

"14 Emphasis should be placed upon the value of the dissemination of the definite, useful and practical knowledge about cancer, and this knowledge should not be confused nor hidden by what is merely theoretical and experimental.

"15 Efforts toward the control of cancer should be made in two principal directions: (1) the promotion of research in order to increase the existing knowledge of the subject,

and (2) the practical employment of the information which is at hand. Even with our present knowledge many lives could be saved which are sacrificed by unnecessary delay."

I find many physicians in the State of New York who believe that no information should be given to the public because, first, we do not know the cause of cancer, second, we have no treatment to offer, that will cure cancer, third, we will create many cases of cancerphobia by talking about cancer to groups of lay people.

These physicians either have forgotten or do not know of the result of the education of the public in the facts about tuberculosis. In 1903 the death rate from tuberculosis in the registration area of the United States was 201.9 per 100,000 population, in 1923 it was 93.6 (mortality statistics, 1923. Twenty-fourth Annual Report, Bureau of the Census, 1926: 37).

In New York State the death rate from tuberculosis per 100,000 in 1900 was 213.7, in 1925 it was 90.9 (supplement to the Monthly Vital Statistics Review, New York State Department of Health, 1926, 6: 209). These results have been achieved very largely through popular education.

We do not know the cause of cancer, but General Gorgas and his co-workers, through the application of the facts determined by the U S Army Board for the Study of Yellow Fever, was able to banish yellow fever from the Canal Zone many years before Noguchi isolated the spirochete.

Many of us are of the opinion that surgery, radium or X-rays properly applied and resorted to early will cure cancer. If we can con-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 11, 1927.

vince lay people and physicians that chronic irritations and low grade inflammatory processes ought to be considered as potentially malignant and treated by appropriate methods until cured, the annual crop of malignant tumors ought to be lessened. The sore that does not heal readily, the persistent indigestion with loss of weight after middle life, the chronic discharge from any of the hollow organs, particularly if it is hemorrhagic, the lump in the female breast, the pigmented mole demand serious consideration as precancerous lesions. We cannot treat these lesions unless the patient calls them to our attention. When they are brought to our attention they merit serious consideration, even though they are resistant to our first efforts. The patient becomes weary of the necessary treatment, the doctor becomes discouraged at the apparent lack of results.

Cancerphobia is common now. Talking about cancer will not produce more cases, it will bring more cases out into the open and a sound appreciation of the situation will definitely reduce the number.

Many of us are convinced of the practicability of attacking the cancer situation by popular education. Let me quote the opinion of some of the leading students of the cancer problem in the United States. "On account of the great interest manifested by the public in cancer (and in fact in everything pertaining to the subject of disease and health) diagnosis is made earlier and operations are consequently more successful on external cancers that can be observed or felt by the physician or the patient himself. This shows the advantage of the public discussion on cancer, cancer week talks, and the effectiveness of newspapers in aiding in this work of education. The surgical treatment of cancer is now much more effective than it was twenty years ago, the operations are much more thorough, and fixed and locally advanced growths involving the primary and secondary lymphatics and those with contact growths or metastases are treated with radiation or other nonsurgical measures, and thus reduce unnecessary surgical mortality" (Charles H. Mayo and William A. Hendricks, *Ann Surg* 1926, 83:357).

"As we have enlightened the public and as the public has come to understand our messages, the percentage of inoperable and hopeless cancer has fallen in the records of the Johns Hopkins Hospital from more than 50 per cent, previous to 1900 to less than 5 per cent since 1920" (Joseph Colt Bloodgood, *Jour Am Med Ass*, 1927, 88:1022).

"Most of the clinical articles on cancer in Medical Journals comment on the late stages in which cases come to treatment. The authors frequently deplore the situation. In this

situation there is no more valuable instrument to use than the daily newspaper. Its ceaseless activity, its wide human interest, its tremendous appeal, reaching the entire community, both lay and professional, can be made to tell the whole story of cancer—how to treat it" (Harry C. Saltzstein, *Jour Am Med Ass*, 1926, 87:347).

"Unless, therefore a patient knows something of the antecedent conditions of cancer, of its early manifestations, of the importance of early treatment, how is he to realize that a medical man should be consulted without the delay of one single day? In Yorkshire I have the happiness to command a band of brothers. The medical and scientific committee of the Yorkshire council has appointed a propaganda sub-committee under the chairmanship of Dr. Hillman. This sub-committee will endeavor to instruct the public in such matters as it is essential for them to know if they are to help us, and will teach them to realize that the only hope of amelioration or of cure in cases of accessible cancer rests upon early diagnosis and skilled surgical treatment" (Sir Berkeley Moynihan, President of the Royal College of Surgeons, England. American Society for the Control of Cancer, 1927:6).

"The American Society for the Control of Cancer has bravely continued its splendid work of disseminating the known facts about cancer and also in making valuable statistical compilations" (John G. Clark, *Progressive Med* 1926, 2:195).

"The laity must be taught by an intensive and continuous nationwide campaign to report all minor lesions, signs or symptoms at the earliest moment and physicians must learn that all cancers begin in so-called minor lesions and become alert to their possibilities so that the laity may expect their potentially cancerous lesions to be removed before they become cancerous.

"On account of the over emphasis on research and the neglect of practical clinical considerations, the medical profession is like a reserve army waiting in the rear for the research generals to give the order to advance, while the enemy is busy at the front dealing torture and death. Every physician should be constantly on guard to prevent the enemy from becoming entrenched" (Carl E. Black, *Jour Am Med Ass*, 1926, 87:1941).

Popular education seems to be a method at hand and practicable in the attack on the cancer problem. The New York State Committee of the American Society for the Control of Cancer feels that it would be equivalent to missing an opportunity if it waited until the cause of cancer is discovered before using an available method which might be successful in reducing the mortality from malignant disease.

## RADIUM TREATMENT IN ANGIOMAS\*

By G ALLEN ROBINSON, M.D., NEW YORK, N Y

**D**URING the past seven years I have treated 276 cases of angiomas with radium. There were 188 females and 88 males, a proportion of a little more than two to one. It is believed, however, that girls are no more prone to angiomas than boys, but that there is more concern about the cosmetic appearance of the girls.

Seventy-seven children were under six months of age, thirty-nine between six months and one year, twenty-five between one and two years, while forty-nine patients were over twelve years of age.

lation, and degeneration of the endothelial cells with leucocytic infiltration of the walls and subsequent distortion of their caliber. If however, the radiation be of mild degree, acting for a short time at prolonged intervals, multiplication of endothelial cells with increased fibrosis of the vessel wall occurs. These changes result in a definite narrowing, perhaps even obliteration of the smaller vessels and it is in this fashion that the cure of angiomas is induced."

Radium exerts a definite specific selective action on the abnormal endothelial cells lining the blood vessels which are at fault in the process. Apparently this is not true of any other therapeutic agent at our command.

\* Read before the Section of Pediatrics Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, May 11 1927

vince lay people and physicians that chronic irritations and low grade inflammatory processes ought to be considered as potentially malignant and treated by appropriate methods until cured, the annual crop of malignant tumors ought to be lessened. The sore that does not heal readily, the persistent indigestion with loss of weight after middle life, the chronic discharge from any of the hollow organs, particularly if it is hemorrhagic, the lump in the female breast, the pigmented mole demand serious consideration as precancerous lesions. We cannot treat these lesions unless the patient calls them to our attention. When they are brought to our attention they merit serious consideration, even though they are resistant to our first efforts. The patient becomes weary of the necessary treatment, the doctor becomes discouraged at the apparent lack of results.

Cancerphobia is common now. Talking about cancer will not produce more cases; it will bring more cases out into the open and a sound appreciation of the situation will definitely reduce the number.

Many of us are convinced of the practicability of attacking the cancer situation by popular education. Let me quote the opinion of some of the leading students of the cancer problem in the United States. "On account of the great interest manifested by the public in cancer (and in fact in everything pertaining to the subject of disease and health) diagnosis is made earlier and operations are consequently more successful on external cancers that can be observed or felt by the physician or the patient himself. This shows the advantage of the public discussion on cancer, cancer week talks, and the effectiveness of newspapers in aiding in this work of education. The surgical treatment of cancer is now much more effective than it was twenty years ago, the operations are much more thorough, and fixed and locally advanced growths involving the primary and secondary lymphatics and those with contact growths or metastases are treated with radiation or other non-surgical measures, and thus reduce unnecessary surgical mortality" (Charles H. Mayo and William A. Hendricks, *Ann Surg* 1926, 83 357).

"As we have enlightened the public and as the public has come to understand our messages, the percentage of inoperable and hopeless cancer has fallen in the records of the Johns Hopkins Hospital from more than 50 per cent, previous to 1900 to less than 5 per cent since 1920" (Joseph Colt Bloodgood, *Jour Am Med Ass*, 1927, 88 1022).

"Most of the clinical articles on cancer in Medical Journals comment on the late stages in which cases come to treatment. The authors frequently deplore the situation. In this

situation there is no more valuable instrument to use than the daily newspaper. Its ceaseless activity, its wide human interest, its tremendous appeal, reaching the entire community, both lay and professional, can be made to tell the whole story of cancer—how to treat it" (Harry C. Saltzstein, *Jour Am Med Ass*, 1926, 87 347).

"Unless, therefore a patient knows something of the antecedent conditions of cancer, of its early manifestations, of the importance of early treatment, how is he to realize that a medical man should be consulted without the delay of one single day? In Yorkshire I have the happiness to command a band of brothers. The medical and scientific committee of the Yorkshire council has appointed a propaganda sub-committee under the chairmanship of Dr Hillman. This sub-committee will endeavor to instruct the public in such matters as it is essential for them to know if they are to help us, and will teach them to realize that the only hope of amelioration or of cure in cases of accessible cancer rests upon early diagnosis and skilled surgical treatment." (Sir Berkeley Moynihan, President of the Royal College of Surgeons, England. American Society for the Control of Cancer, 1927 6).

"The American Society for the Control of Cancer has bravely continued its splendid work of disseminating the known facts about cancer and also in making valuable statistical compilations" (John G. Clark, *Progressive Med* 1926, 2 195).

"The laity must be taught by an intensive and continuous nationwide campaign to report all minor lesions, signs or symptoms at the earliest moment and physicians must learn that all cancers begin in so-called minor lesions and become alert to their possibilities so that the laity may expect their potentially cancerous lesions to be removed before they become cancerous.

"On account of the over emphasis on research and the neglect of practical clinical considerations, the medical profession is like a reserve army waiting in the rear for the research generals to give the order to advance, while the enemy is busy at the front dealing torture and death. Every physician should be constantly on guard to prevent the enemy from becoming entrenched" (Carl E. Black, *Jour Am Med Ass*, 1926, 87 1941).

Popular education seems to be a method at hand and practicable in the attack on the cancer problem. The New York State Committee of the American Society for the Control of Cancer feels that it would be equivalent to missing an opportunity if it waited until the cause of cancer is discovered before using an available method which might be successful in reducing the mortality from malignant disease.

## RADIUM TREATMENT IN ANGIOMAS\*

By G ALLEN ROBINSON, M.D., NEW YORK, N Y

**D**URING the past seven years I have treated 276 cases of angiomas with radium. There were 188 females and 88 males, a proportion of a little more than two to one. It is believed, however, that girls are no more prone to angiomas than boys, but that there is more concern about the cosmetic appearance of the girls.

Seventy-seven children were under six months of age, thirty-nine between six months and one year, twenty-five between one and two years, while forty-nine patients were over twelve years of age.

lation, and degeneration of the endothelial cells, with leucocytic infiltration of the walls and subsequent distortion of their caliber. If however, the radiation be of mild degree, acting for a short time at prolonged intervals, multiplication of endothelial cells with increased fibrosis of the vessel wall occurs. These changes result in a definite narrowing, perhaps even obliteration of the smaller vessels and it is in this fashion that the cure of angiomas is induced."

Radium exerts a definite specific selective action on the abnormal endothelial cells lining the blood vessels which are at fault in the process. Apparently this is not true of any other therapeutic agent at our command.

The radium dosage and method of application depends upon the type and size of the lesion. There were twenty-three cases of portwine marks in this series. Mild or suberythema doses with beta and gamma radiation are used. The interval between treatments should be from four to six weeks. Great care must be taken to avoid inflammatory reaction, which would be liable to produce irregular discoloration of the lesion, scarring and telangiectasia. After six to ten treatments there should be a distinct fading in the color of the lesion and the skin remains

ularly of the lip, in which plaque radiation had failed, the lesion responded easily to the interstitial method. In cavernous angiomas 2 to 4 centimeters in diameter radiation at one centimeter distance is advised in order to obtain a proper depth dosage, and to avoid over action at the surface of the tumor. One hundred milligrams of gamma radiation at one centimeter distance may be applied to an area five centimeters square for three hours. In huge cavernous angiomas radiation at three to five centimeters distance with a larger amount of radium is

Fig 3 Extensive Angioma Right Side of Face.

Fig 4 Twenty-two Months after Radium Treatment

apparently normal. Complete removal of portwine marks, as in raised vascular nevi, is not to be expected, but with the lesion two or three shades lighter than originally, together with the use of cosmetics, fairly satisfactory results are achieved.

The tuberous angiomas varied from a superficial, slightly elevated or strawberry mark to massive infiltrating pulsating growths. In the small flat lesions a 50 milligram radium tube screened with one millimeter of brass and one millimeter of rubber may be applied to the surface of the lesion for one-half hour, or a standard 10 milligram radium plaque properly screened may be used. The treatments are repeated at intervals of from three to four weeks. In small cavernous angiomas the insertion of 10 milligram platinum radium needles one-half centimeter apart and allowed to remain for our hour gives splendid results. In several cases, partic-

necessary to affect the deeper portions of the growth.

The majority of angiomas are present at birth or shortly afterwards. The results indicate that the lesions should be exposed to treatment in the first six months of life, as the walls of the blood vessels become thicker and more organized in the older groups and are, therefore, more refractory to radiation. Bleeding and ulceration were apparently no contraindications to treatment. These conditions were very much decreased after the first application of radium.

The number of applications varied from three to five in small angiomas, to twenty to thirty in the most extensive cases. There were no untoward after effects following the treatments. The final results, except in a few instances, may be described as excellent. In one case, a young man, the entire left cheek—skin, muscles, mucosa and antrum—were involved with widely dilated

blood vessels. The result in this case was not satisfactory. In another case, a girl fifteen years of age, with a large cavernous angioma of the orbit, there was danger of over radiation to the eyeball.

In general, however, radium may be considered the treatment of choice in angiomas, and supplants in a large measure the scapel, carbondioxide snow, caustics and caudery.

### CERTAIN PATHOLOGICAL CONDITIONS OF THE CERVIX UTERI TENDING TOWARD CANCER\*

By JAMES N WEST, M D, NEW YORK, N Y  
Professor Diseases of Women, N Y Post Graduate Medical School and Hospital

HUXLEY said "Sit down before a fact as a little child. Give up every preconception and prejudice. Be ready to follow wherever fact may lead, or you will learn nothing." No subject of research requires this spirit more than that of cancer. We must get the facts and follow where they lead.

A brief epitome of the history of cancer research and a comparison of former views with those of the present is helpful.

We might say that the modern conception of cancer began with Laennec 1804. Cancer of the breast was carefully studied by Lobsten, Cruvelhier, Velpeau, Astley Cooper and others. In 1838 the cell theory was established by Schleiden and Schumann 1839, and had been applied to tumors by Johannes Muller 1838, who attributed cancer to new specific cell formation within the connective tissue of an organ, with profound affection of the whole system. He was the first to demonstrate nuclear epithelium in cancerous tissues.

Following these discoveries came the attempt to discover specific cells.

From 1847-1852 valuable contributions were made by von Bruns who stressed the role of the lymphatics in spreading cancer, by Hanover who named and described epithelioma, and by Bidder who described and named cylinder epithelioma.

Remak 1841-52 established the growth of new tissues by the division of pre-existing cells. This knowledge was applied to pathological formations by Virchow, who in 1855 described canceroid, and later cancer and heteroplasic tumors as proliferations of connective tissue cells, due primarily, both in cancer and its metastases, to some irritating element or secretion. Virchow's description thus stands to-day with the riddle unsolved.

In 1872 Conheim advanced the theory of tumor formation from a rest or group of misplaced

foetal cells, which became activated through some cause unknown. The adoption of this theory has been a serious hindrance to the advancement of cancer research.

Hausemann Ribbert and others about 1904-11, insisted upon a modification of Conheim's theory to the effect that undifferentiated epithelium may proliferate into cancer.

(1) "Arthur Hanan of Zurich made the real start in 1889 in experimental transplantation of epithelioma in white rats. His work was preceded by Novinsky in 1876, Weber in 1878, Cornil and others, but remained unrecognized until its confirmation by Moran 1894 and Barel 1903.

"Inoculability of sarcoma in rats was established by Leo Loeb in America 1901, and Jensen in Denmark 1903, who carried rat sarcoma through forty generations of rodents without change in microscopic structure.

"In 1911-14 Peyton Rous demonstrated the specific character of sarcoma in the mesoderm of Plymouth Rock chickens by experimental transplants and inoculation of cell free filtrates. Extravital cultivation of malignant tissues was established by Carrel and Burroughs 1911, extended to an indefinite period by feeding the culture with chicken muscle by A. Fischer 1925, while Drew showed that malignant tumor cells produce a growth inducing substance (Carrel's trephone) as in the case of injured normal cells.

"Bazon 1912, Yamagiwa and Ichagawa 1916 produced epithelioma in rabbits by injection of tar products. Leitch produced carcinoma, epithelioma and sarcoma in animals by potassium arsenate paraffin and other substances. X-ray and radium have produced cancer. Nematode worms have produced cancer as first noticed by Borel 1910 and demonstrated by Fibiger in 1914.

"Rhodenburg got sarcoma in rats by feeding with cystocercus fasciolaris.

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 10, 1927.

"Other experiments have proved the development of cancer through chronic irritation. This, however, leaves the subject wide open for chronic irritation is a factor composed of many puzzling elements. Cystology seems to offer the most promising field for the solution of the problem."

(2) Montrose Burrows states that "The actual neoplastic change of normal cells into cancer cells is the essence of the cancer problem. Further, cancer in the light of certain facts cannot be a reversion of the cell to an embryonal type, but rather the return of the cell to its more primitive state or a release of it from those forces dominating it in the organism."

"The present view of cancer abrogates the theory of Conheim for this type of tumor. The writer has long felt that one of the factors in the causation of cancer of all forms is one or more specific microorganisms."

"There are close analogies in the development of certain tumors in which specific microorganisms are known factors. Some of these are the gumatous tumors (syphilis), tubercles (tuberculosis), tubercles of leprosy, condylomata (gonorrhea and syphilis), and other tumorous developments from known specific infections."

"The writer believes that light may be thrown upon the cancer problem by further study of cell reactions in the above class of cases."

"The existence of cancer localities of special family susceptibility of chronic irritations as factors, point strongly to a specific cause. The great variety which chronic irritation takes is no argument against a specific agent, as the chronic irritation may produce some condition or substance favorable to the entrance of the specific cause."

"The fact that metastases are all the same type as the mother tumor, is also no argument against specificity, as the migrated cancer cells would doubtless be infected. The problems affecting cancer and non-malignant growths are to some extent identical but differ in important particulars. The finding of a specific organism for cancer would not solve the problems of benign growths, nor would the finding of an organism for one type of malignant disease necessarily solve the problem for other types, but it would go a long way toward doing so."

"The above views are not those of a majority of cancer researchers."

(3) A quotation from Willy Meyer's presidential address to the Cancer Research Society will give a fair expression of the majority of views of the present.

1 "From all the uncertainties that still surround the problem of cancer, there stands out at least one observation which, by general agreement has been universally accepted as a definitely established fact, that the cancer cell was at one time a normal cell,—a cell of that particular tissue in which the cancer arises."

2 "To the process of transformation of the

cells from one state to the other non specific factors such as mechanical, thermal, actinic, chemical, endocrine, heredity, stand as inciting but incidental causes."

3 "Current experimental production of primary cancer by various non specific means makes the search for the specific cancer agent appear as no longer advised, and seems to prove that irritation is ordinarily the starting point of processes tending in the direction of cancer."

4 "As nearly as anything can be certain in medicine there is no cancer contagion, i.e., infection."

5 "Observations seem to prove that cancer is in every instance an individual experience."

6 "More than one individual may receive a non specific inciting factor from the same source and, then, independently by reason of the same, may or may not develop cancer."

7 "Around a source disseminating directly or indirectly through intermediate hosts, one or more inciting factors, cancer houses, cancer towns, cancer districts, may grow up."

Other conclusions in this article relate to treatment. In the opinion of the writer the work of Gye and Barnard, Peyton Rous, John Nuzum, and others shows a serious and more or less successful attempt to establish a specific cause for cancer.

The outlook is most hopeful of solving the problem, but there is ample room for more research both in cytology and bacteriology.

The means for research have made great strides, the ability to create animal cancer at will for purposes of study, the ability to cultivate living cells outside the body, where they may be independently studied, the improved methods of microphotography, the advances in biochemistry, the increased facilities in bacteriological technique,—all tend to make possible investigations which should make the advance much more rapid than in the past. Up until the present time the practical outcome of all the investigations is a limited and unsatisfactory treatment and we have (4) to expect one out of every eight women, and one out of every twelve men to die a miserable and lingering death from cancer. The prevention therefore, becomes one of the most important and serious problems of mankind. Cancer of the uterus and especially of the cervix uteri, is one of the common forms met and it is the belief of the writer that there is here one of the largest and most satisfactory fields of cancer prevention, and that this useful field of endeavor is much neglected.

Laceration of the cervix and its accompanying hypertrophic changes and reparative efforts seems to be one of the most important factors in the chronic irritation of that organ, and if anything is proved in cancer development it is that chronic irritation is a factor. The following statistics strongly support this view.

Some interesting facts are revealed by statistics in 200 cases of carcinoma of the cervix which the writer has gathered at the New York Post-Graduate Hospital, being his own cases and those of several other surgeons

The age incidence is as follows

20—30 yrs	10 cases or	5%
30—40 yrs	50 cases or	25%
40—50 yrs	74 cases or	37%
60—70 yrs	19 cases or	9½%
over 70 yrs	1 case	

It will be seen from the above that after 40 years, 140 cases—or 74%—occurred In regard to social state, 26 were single (13%) In regard

oma of the cervix, 7 had not borne children."

Gusserow gives the age distribution in cancer of the uterus in 3,471 cases as follows

40—50 yrs	1196
50—60 yrs	856
30—40 yrs	770
60—70 yrs	340
70 and over	193
20—30 yrs	114
17—19 yrs	2

This brings out the interesting fact that after 40 years of age 2,822 out of 3,471 cases of cancer of the uterus, occur more than two-thirds of all the cases

Fig I—A low power photomicrograph of a cervix whose right edge shows an ulceration or erosion.

to maternity, 58 had never been pregnant (29%) This includes single cases as well as sterile married women This is a revelation to the writer as 74% of cases occurred after 40 years of age, and it is to be assumed that a large majority of women are married at that time so that it would indicate that single women (nulliparæ) are as susceptible to cancer of the cervix as married women, which is contrary to the usual belief and would require more study and further statistics before being accepted

The 200 cases had 330 children,—rather a small average One woman bore 14 children and one 10, but the rule is small number or sterility Sixty married women had no children.

(5) Lynch "The great majority of cases of cancer of the cervix occur in women who have borne children Occasionally they occur in virgins, but usually in women who have had dilatation of the cervix. Sampson found that in 412 uterine carcinomata only 3% were nulliparæ Williams in 334 cases found 4% were in nulliparæ Cullen found that in 64 cases of carcin-

Then why not give every woman a searching examination at 40 years of age with the determination to correct any existing possible cause of cancer?

The writer might report a large series of cases of the same type but one will suffice It is as follows

July 12, 1920 Mrs H R, age 49 yrs Married 33 yrs 11 children, 7 living No instrumental deliveries No operations Menstrual history Regular, 28 day type, flows 7 days freely This has always been the type Two years ago began to bleed whenever she had intercourse One year ago began to have treatment and improved in that particular Has had severe itching about the vulva at times *Diagnosis* Lacerated cervix and perineum Part of the cervix—posterior and right—suspicious of malignancy Operation advised Frozen section of diseased cervix to be made to determine whether to do amputation or hysterectomy *Operation*, Aug 2, 1920—Emmet amputation of the cervix and author's repair of perineum

"Other experiments have proved the development of cancer through chronic irritation. This, however, leaves the subject wide open for chronic irritation is a factor composed of many puzzling elements. Cystology seems to offer the most promising field for the solution of the problem."

(2) Montrose Burrows states that "The actual neoplastic change of normal cells into cancer cells is the essence of the cancer problem. Further, cancer in the light of certain facts cannot be a reversion of the cell to an embryonal type, but rather the return of the cell to its more primitive state or a release of it from those forces dominating it in the organism."

"The present view of cancer abrogates the theory of Conheim for this type of tumor. The writer has long felt that one of the factors in the causation of cancer of all forms is one or more specific microorganisms."

"There are close analogies in the development of certain tumors in which specific microorganisms are known factors. Some of these are the gumatous tumors (syphilis), tubercles (tuberculosis), tubercles of leprosy, condylomata (gonorrhea and syphilis), and other tumorous developments from known specific infections."

"The writer believes that light may be thrown upon the cancer problem by further study of cell reactions in the above class of cases."

4 "As nearly as anything can be certain in medicine there is no cancer contagion, i.e., infection."

5 "Observations seem to prove that cancer is in every instance an individual experience."

6 "More than one individual may receive a non specific inciting factor from the same source and, then, independently by reason of the same, may or may not develop cancer."

7 "Around a source disseminating directly or indirectly through intermediate hosts, one or more inciting factors, cancer houses, cancer towns, cancer districts, may grow up."

Other conclusions in this article relate to treatment. In the opinion of the writer the work of Gye and Barnard, Peyton Rous, John Nuzum, and others shows a serious and more or less successful attempt to establish a specific cause for cancer.

The outlook is most hopeful of solving the problem, but there is ample room for more research both in cytology and bacteriology.

The means for research have made great strides, the ability to create animal cancer at will for purposes of study, the ability to cultivate living cells outside the body, where they may be independently studied, the improved methods of microphotography, the advances in biochemistry, the increased facilities in bacteriological technique,—all tend to make possible investigations which should make the advance much more rapid than in the past. Up until the present time the practical outcome of all the investigations is a limited and unsatisfactory treatment and we have (4) to expect one out of every eight women, and one out of every twelve men to die a miserable and lingering death from cancer. The prevention therefore, becomes one of the most important and serious problems of mankind. Cancer of the uterus and especially of the cervix uteri, is one of the common forms met and it is the belief of the writer that there is here one of the largest and most satisfactory fields of cancer prevention and that this useful field of endeavor is much neglected.

Laceration of the cervix and its accompanying hypertrophic changes and reparative efforts seems to be one of the most important factors in the chronic irritation of that organ, and if anything is proved in cancer development it is that chronic irritation is a factor. The following statistics strongly support this view.

mends repair on the 6th day. Both are enthusiastic about the ease with which repair can be done and the results.

The writer does not feel that the proper time for repair of the cervix is a settled question but thinks that both cervix and perineum should be repaired within the first three months, and advocates immediate repair of the perineum.

If the perineum has been repaired immediately it would not bear the strain of the speculum used in repairing the cervix on the 9th day.

*Endocervicitis* Opinions vary widely as to

of various pelvic inflammatory conditions, and has advised his operation of tracheloplasty for its relief.

There is no doubt, however, in the mind of the writer, that endocervicitis alone may bring about a condition (rarely) favoring the development of cancer. Such a case was seen recently where the patient was a nullipara. Notwithstanding treatment for endocervicitis, a papillomatous condition around the os developed which was cauterized. In a short time the same appearance recurred. An amputation was done about a year

Fig. III—Papillomatous development in the ulcerated area, and early carcinomatous invasion of the tissue as indicated by the large circle filled with epithelial cells.

what extent this condition is a factor in producing cancer. In endocervicitis, uncomplicated by laceration, the writer's observations do not suggest that it is a very important factor. Lynn L. Fulkerson (7) in a clinical study of 1,039 cases of endocervicitis treated at the Cornell Clinic remarks in his summary "Clinically no evidence was found that endocervicitis is a precancerous lesion." One case of cancer was found.

(8) On the other hand Sturmdorf believes that it is a most important cause of cancer and

ago and a recent examination showed a healthy vaginal vault and a cessation of the leucorrhœa.

Endocervicitis undoubtedly forms a difficult problem and one which up to the present time, offers no uniform method of cure. The chief methods of relief offered are local antiphlogistic treatment,—packing the cervix up to the internal os with gauze saturated with 20% argyrol, 2% mercurochrome or other antiseptic,—suction instruments with antiseptic spray,—peripheral tissue injections with antiseptics,—a dia-

*Pathological report by Dr Ward J MacNeal*  
 Frozen section No evidence of malignancy  
 Gross one piece of cervix amputated by circular incision 55 x 40 x 22 mm External os patulous 20 x 15 mm irregular, on one side the mucous membrane is red and contains several translucent cysts 2-5 mm in diameter On section a cyst 12 mm in diameter is exposed Microscopic Squamous cell epithelium, thickened and somewhat irregular Glands are dilated and cystic, quite marked chronic inflammatory reaction, some hemorrhagic areas No evidence of malignancy

I herewith present some microphotographs of a cervix of this type, which, right or wrong, the writer terms precancerous

This case is presented in full for the purpose of illustrating what may and should be done in view of our present knowledge of cancer Such cases are very common but should not be allowed to come to such a danger point The writer advocates Emmett's amputation in all cases of the type of cervix above described

The pathological processes which gradually occur make lacerated cervix a much more danger-

Fig II—A high power view of the ulcerated area of Fig I, showing papillomatous developments and an invasion of glands with epithelium into the tissue.

nancy *Diagnosis* Erosion and chronic cervicitis

*Examination* February 15, 1921, negative No erosion of cervix No more metrorrhagia or bleeding on coitus To have another examination in six months

*Examination* June 28, 1921 patient fears she is pregnant No evidence of it Cervix looks healthy To come again for examination of cervix December 10, 1926, patient came for examination Patient had menopause 4 years ago *Examination* shows cervix to be perfectly healthy

ous source of cancer than simple endocervicitis Though the latter may become the chronic irritating factor in cancer causation, this has seldom occurred in the writer's experience The early repair of lacerated cervix is probably one of the most important prophylactic measures against cancer

(6) In regard to this M H Williams, Los Angeles, Cal, in a study of 200 recent deliveries found 86% of lacerations of the cervix and advocated repair from the 7th to the 9th day Coffey has chosen the 9th day post par tem for a number of years as the time of choice Hirst recom-

## THE CANCER EXHIBIT

The Cancer Exhibit of the Medical Society of the State of New York, described on page 997 of this JOURNAL, demonstrated that there is but little of the spectacular connected with the disease, but much that calls for patience and for skill of the highest order. The disease is insidious, and no germ or serum or characteristic sign betrays its presence. Only the microscope makes an obvious revelation of its existence in the early stages when it is curable. Yet to the keen physician, guarding

the health of confiding patients, there appear signs and symptoms which cause him to redouble his watchfulness, and to apply every possible means for recognizing and expelling the disease in its beginning.

The elementary principles of cancer knowledge are few in number and easy to comprehend when they are compared with those of other diseases—tuberculosis or syphilis, for example, yet the diagnosis and treatment of no other disease calls for

thermy, electric cautery, and operations—amputation or tracheloplasty

In regard to the latter, Harvey B Matthews (9) has presented some interesting statistics in which the results of his tracheloplasty cases with the amputations done for the same reason by another surgeon and shows about the same number of cures

The writer has had cases where erosions and endocervicitis have disappeared after an operation for retroversion, in which local treatment had failed to cure. Thus indicating that at times disturbed circulation may be the important factor

Acute gonorrheal endocervicitis will often clear up quickly through packing the cervix with gauze soaked with 30% argyrol solution

Cervical polyp may be a source of chronic irritation and frequently cause more or less continuous bleeding. They may take the form of fibromyomatous polyp, adenomatous and sarcomatous polyp. In any case they should be removed and subjected to microscopic examination

The commonest form is so-called mucous polyp, which often shows a microscopic structure closely resembling malignancy

The writer has removed many of these in the course of the last thirty years and does not recall any case in which malignant growth afterward occurred in the uterus

Elliott Bishop (10) reporting a case of malignancy in a cervical polyp, states that Dickinson reports 106 recorded cases of cervical polyp in private practice, most of which had histologic examinations. Only one was malignant and this was cured by amputation of the cervix by the Byrne cautery method. Dr S H Geist reports that as a result of routine examination of all cervical polypi at the Mt Sinai Hospital malignant development is extremely rare. Sarcomatous polyp of the cervix is rare but very fatal. The writer has seen two cases—one in the service of Dr B Emmet about 20 years ago, while acting as his assistant. The first operation consisted in removal of the polyp, which quickly recurred, on the second removal the specimen was subjected to histologic examination and found to be sarcoma. This was immediately followed by hysterectomy. The patient died in a few months from recurrence in lungs

The second case was that of the writer and the sarcomatous nature of the polypus was immediately discovered and hysterectomy per-

formed. This patient also died in a few months from recurrence in the lungs

Other causes of irritation in the vagina are foreign bodies, pessaries, stems, etc., which no doubt sometimes cause cancer. Another cause of chronic irritation at times is vaginal bands, especially those which are congenital

## CONCLUSIONS

1 Finally the writer would say that it is particularly important that women past thirty-eight years of age should have periodic health examinations, not only to determine their general condition, but in particular the condition of their pelvic organs

2 That lesions of childbirth should receive early attention and not be allowed to go until the time when the woman is supposed to have finished her childbearing

3 That those cases which have extensively diseased conditions of the cervix as a result of lacerations and endocervicitis, should have amputation of the cervix, preferably by the Emmet method. The amputation in those who have passed the childbearing period should extend to the internal os, and those who may yet bear children should have one-third of an inch of the cervix below the internal os left

4 If all women past forty could have their cervixes put in healthy condition, perhaps two-thirds of the cases of carcinoma of the cervix could be prevented

5 Removal of the cervical polyp and relief of chronic irritations of the cervix and vagina should receive prompt and effective attention

## THE CANCER EXHIBIT

The Cancer Exhibit of the Medical Society of the State of New York, described on page 997 of this JOURNAL, demonstrated that there is but little of the spectacular connected with the disease, but much that calls for patience and for skill of the highest order. The disease is insidious, and no germ or serum or characteristic sign betrays its presence. Only the microscope makes an obvious revelation of its existence in the early stages when it is curable. Yet to the keen physician, guarding

the health of confiding patients, there appear signs and symptoms which cause him to redouble his watchfulness, and to apply every possible means for recognizing and expelling the disease in its beginning.

The elementary principles of cancer knowledge are few in number and easy to comprehend when they are compared with those of other diseases—tuberculosis or syphilis, for example, yet the diagnosis and treatment of no other disease calls for

more knowledge of detail and broader experience. Fortunately the means of diagnosis and treatment are available to every physician and patient of New York State. The great lesson of the Cancer Exhibit is that general practitioners, when they

are confronted with uncertain diagnoses, should always have cancer in mind instead of a possible diagnosis of last resort, and should take prompt steps to secure an early diagnosis and prompt treatment.

### A NEW DEPARTMENT

A new department called Medical Ware begins in this issue of the JOURNAL. It will be devoted to wares that are sold especially to physicians. The word wares has an Anglo-Saxon lineage that is both ancient and honorable, and means anything that is a common article of trade. Some articles, such as microscopes and cystoscopes are products of long development and calculations in the higher mathematics, and others, such as insulin and radon seeds, are the crowning results of the most skilled scientific research. But these products are sold to physicians just as other wares are sold, and physicians often use them while giving little thought to their origin, whether it be the inventive mind of a mill hand, or the result of long research by the highly trained post-graduate physicist.

A modern doctor could not practice medicine if he could not obtain every variety of medical ware in the open market, and manufacturers could not afford to develop the means of producing and distributing standardized products if the physicians did not buy or prescribe their wares.

The new department is designed to bring about a mutual understanding between physicians and manufacturers. Physicians are always interested in the processes by which medical wares are made, and in the methods by which their standards are determined and maintained.

Manufacturers have shown a deep interest in the new department, and those who have been approached have given the editors every possible facility for observing the preparation of their products, and ascertaining the scientific principles of their manufacture and use.

The first article of the series appears on p 1045 and is on radon seeds, which contain exact doses of the radiations or emanations of radium. The availability of radon seeds will doubtless be a great stimulus to the early diagnosis and treatment of cancer, for physicians can now feel that radium is within the reach of every patient. Moreover, when patients come to know more about the availability of radium treatment, they will be the more ready to seek an early diagnosis and treatment.

### THE CATTARAUGUS COUNTY HEALTH DEPARTMENT

The Supervisors of Cattaraugus County established the only County Health Department in New York State five years ago under an agreement that the Trustees of the Milbank Memorial Fund should contribute the greater part of the cost of the Department, and that the State Charities Aid Association should have a dominant part in directing its activities. The Department was conducted along the lines of the modern Health Department of a city with the stated purpose of demonstrating a working plan which other counties might follow in establishing county health departments.

The Department was divided into ten bureaus, as follows:

- 1 General Administration
- 2 Records and Vital Statistics
- 3 Public Health Nursing
- 4 Tuberculosis
- 5 Laboratories and Communicable Diseases
- 6 Maternity, Infancy, and Child Hygiene
- 7 Health Education
- 8 Nutrition
- 9 Venereal Diseases
- 10 Sanitary Inspection

The County Health Department also supervised the examination of school children in cooperation with the school physicians appointed by the school districts. The supervisor of the work is paid by the Milbank Fund.

Cattaraugus County also has a County Tuberculosis Hospital which is operated by its own special board and under an appropriation which is separate from that of the County Department of Health. The appropriation last year was \$40,000.00 for maintenance and \$4,000.00 for repairs.

Cattaraugus also continued the system of a local health officer in each city, village, and township, according to the methods of conducting public health work in the other counties of New York State. There were 25 local health officers in Cattaraugus County and these all continued to function, and were important factors in the public health work in the County. The reports of the accomplishments of the Cattaraugus County Health Department have usually included the results attained by the local health officers who still bear the greater part of the burden of communicable disease control and sanitary inspection.

The cost of the Cattaraugus County Health

Department for the year 1926 is stated in the Annual Report of the Board of Supervisors as follows

"Your Board last year appropriated \$56,060—one-half of which, or \$28,030—was refunded to the County and the State. Therefore, the net cost of the Board of Health to the County was \$28,030. Your appropriation of \$28,030—brought to the County not only an equal sum from the State, but secured for Cattaraugus County from the Milbank Memorial Fund the sum of \$97,000—which was allocated to the various agencies for health work in the County."

This report indicates that the County Health Department cost \$153,060—during the year 1926. No figures are available regarding the cost of the local boards of health.

The sum of \$44,000 appropriated to the Tuberculosis Hospital should be added to the net cost of the County Health Department so that \$72,000 of public funds were paid for the public health work conducted by the county.

The five-year agreement of Cattaraugus County with the Milbank Memorial Fund and the State Charities Aid Association expires on December 31, 1927, and there is much discussion in regard to its renewal. The Cattaraugus County Medical Society considered the general proposition of a County Health Department at a special meeting

held on August 4, 1927, and a report of its action is printed on page 1041 of this JOURNAL. A careful reading of that report shows that the physicians of Cattaraugus County are in favor of broad activities in public health, and that specifically they favor the following activities:

1. A County Health Department to be conducted entirely by the people of the county.

2. A rearrangement of the bureaus, and especially the continuation of the laboratory, and the tuberculosis and venereal disease work by the county.

3. The continuation of the system of local boards of health and health officers.

4. A greater participation of the general practitioners in the practice of public health.

The plan of the physicians of Cattaraugus County does not differ greatly from that proposed by other progressive rural counties—for example, that of Suffolk County, printed on page 563 of the May 15th issue of this JOURNAL. The most hopeful element in public health work in Cattaraugus County is the statement in the official Bulletin of the County Medical Society that "The Committee on Public Health and Public Relations is at present hard at work on a comprehensive program of sound and economical public health work for this County." Doubtless it will work out a satisfactory program.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*Cancer of the Breast*—The fundamental principles of the surgical treatment of cancer were well understood two decades ago, and at that time a wealth of experience over a period of years had been accumulated to demonstrate the efficiency of surgery when a new growth was removed early and completely.

The results of operation for cancer of the breast were discussed editorially in this JOURNAL for September 1907, as follows:

"The treatment of cancer of the breast has been brought to a position of much hopefulness and satisfaction, notwithstanding the many discouragements through which it has passed. Surgeons are agreed as to the therapy, and all wise physicians cooperate with them. The results now secured in this, once nearly hopeless disease, stand as one of the great triumphs of modern medicine. The fatalities are among those who have deferred too long, but even for these surgery attempts something. In the discussion upon this subject before the American Surgical Association

at its last meeting, it was shown that the duration of the disease exerts much influence on prognosis, that extensive operations with wide removal of skin gave the greatest freedom from local recurrence, and that incomplete operations in early cases yield better results than extensive operations in cases which are well advanced.

"The improved results secured in the treatment of this disease have not been so much the triumph of antiseptic surgery, as has been the case in so many diseases, but rather in the greater extent and completeness of the operation as now practiced. Surgeons now report eighty per cent of cases operated upon remaining cured beyond the three-year limit. The technic of the treatment of this disease has reached a high state of perfection, further hope in reducing the mortality depends upon the education of the general practitioner and of the public to the necessity of early operation, and the elimination of those delusive practices which can be called by no more genteel name than the criminal puttering with cancer of the breast."

# MEDICAL PROGRESS

**Malignant Diphtheria**—Sanitary Councillor Canon of Berlin discusses in the *Deutsche medizinische Wochenschrift*, July 8, 1927, under the title "Septic Diphtheria," a type of the disease in which the mortality is high and serum inactive, this is regarded by some as hypertoxic while others look upon it as a mixed diphtheria-streptococcus infection. He recalls an episode of this kind in 1892-3 in which in the beginning half of the children died and medicine seemed powerless. It was just at this juncture that the Behring serum received its first tryout (in the Moabit Hospital). The combined use of serum and tracheotomy appeared to produce some improvement in the mortality, but control figures showed that the virulence was already waning. The first use of the serum was in absurdly small doses of course. We seem now, Canon says, on the verge of another of these waves of highly virulent diphtheria, and several physicians after exhibition of large serum doses appear to be discouraged with the result, but blood tests made now, like those in 1892-3, show the presence of virulent hemolytic streptococci which, of course, cannot be antagonized by the diphtheria serum. The children really perish of streptococcic sepsis and not from the action of the diphtheria toxin. For the treatment of these cases convalescent serum should be our sheet anchor, and if this is not obtainable a polyvalent streptococcus serum, in the author's opinion, is not indicated but rather a vaccine made from cultures obtained from the throat of the patient. In the meantime a diphtheria-streptococcus antiserum, calculated to meet the situation should be prepared. There is no allusion to a trial of scarlet fever serum or of any other univalent streptococcus serum although we know that different strains of these hemolytic cocci may sometimes give positive results even if theoretically not indicated.

According to H. Finkelstein and E. Konigsberger of the Berlin Children's Hospital, writing in the same journal for July 15, there is nothing new about the type for it is our familiar mixed infection with streptococci which was formerly pronounced to be an illusion, but quite recently has been rehabilitated by the discovery at autopsy of hemolytic streptococci in the organs. With this changed viewpoint there has been a movement to treat these cases with streptococcus serum and in the form of a special antitoxin, for devising which Meyer and Joseph claim the credit, they having been at work on this idea for about 5 years. The authors have used this preparation along with ordinary diphtheria antitoxin in nine selected cases treated in the past 6 months. Nine others received only

ordinary diphtheria serum. In the series treated with both sera, seven of the nine recovered, while with the diphtheria serum alone there was but one recovery. All of the cases in this test were of the gravest type with much fetor and cervical swelling, signs of renal implication and, in a minority, acute and profuse hemorrhages. In the successful series the serum was not applied until the second week, while in the unfavorable one the antitoxin was injected in the first week. Ordinarily under the present epidemic conditions these patients should all have succumbed.

**Natural Immunity to Infection as Observed in Natives of the Tropics**—Writing in the *Southern Medical Journal*, July, 1927 (xx, 7), R. W. Mendelson argues that natural immunity to infection is developed by persons living in a highly infected environment under natural conditions. The tropical native has a far richer intestinal flora than has one living under modern sanitary conditions. This has so increased his resistance that he is able successfully to overcome a tendency to acute appendicitis, and in surgical operations he survives infection which would ordinarily result fatally. A ten years' sojourn in Bangkok has enabled the author to compare the typhoid fever ratio of the first three years of this period with the last three years, this he found to be as 1 to 10, and the same applied to dysenteries and cholera. The city of Bangkok is evenly divided by a large river. The east side of the city has been supplied with pure water since October, 1914, while the west side has always had polluted water. In the 1919 epidemic of cholera, though the mortality per thousand was higher on the west side, the chances of infection being greater, the case mortality was actually lower. The explanation is that the people who were provided with pure water gradually lost their natural immunity to pathological intestinal bacteria. In regard to typhoid infection, an endeavor was made to determine to what extent the native Siamese harbored immune bodies in the blood. To this end the author examined some six hundred patients in a Bangkok institution, with the finding that 15.5 per cent of these subjects possessed agglutinins in their blood. In this institution about 60 per cent of the inmates are permanent and have lived under very good sanitary conditions for years. Practically 99 per cent of the positive reactions were in new patients, indicating that the older inmates had lost their one-time natural immunity to typhoid. The author concludes that clinical experience in the tropics indicates that the new-

born inherits sufficient general-infection immunity to protect it until more specific immunity is developed as the result of a more or less continuous vaccination with infected food and water. He suggests that when instituting sanitary reforms in a virgin field, both food and water should come under control at the same time, otherwise there is danger of increasing the susceptibility to intestinal infection as a result of decreasing natural immunity. Although a material degree of protection is acquired as a result of living in a highly infected environment under natural conditions, degenerative diseases develop earlier. They result from overtaxation of the bodily tissues in developing and maintaining general-infection immunity.

**Amebiasis**—J. H. Musser, writing in the *American Journal of the Medical Sciences*, July, 1927 (cxcv, 1), analyzes a series of 51 cases of amebiasis occurring in the Charity Hospital in New Orleans during the past year. Among these cases the greatest incidence occurred in the age period from 31 to 40 years. The disease is very rare in patients under 16 and over 60, and is a clinical curiosity in a child. Of the 51 patients 46 were males. The majority of the patients apparently contracted the disease in Louisiana. They complained quite regularly of diarrhea lasting from three to twelve years, in one case thirty years. Proctoscopic examination was carried out in all cases, and revealed the usual typical picture of proctitis, thus showing the relation of dysentery to ulcerated rectum. Various types of treatment were employed—yatren, stovarsol, emetine, and ipecac alone and in combination with stovarsol. Yatren was most successful and was employed in 24 cases. The author follows the classification of Dobell and Low, which divides the disease into four clinical groups: carrier, general amebiasis, amebic diarrhea, and amebic dysentery. Carriers without symptoms are more numerous than individuals having diarrhea or dysentery, and as they are more or less continuously passing cysts they constitute the main source of infection. In general amebiasis there may for a long time be no definite symptoms, merely easy fatigability, absence of a feeling of well-being, and a consciousness of the intestines. There is often arthritis and sometimes definite fixation of terminal phalangeal joints without pain. Kofoed and his co-workers have suggested that most cases of arthritis are due to amebiasis. When a patient with general amebiasis develops well marked intestinal symptoms he passes into the amebic diarrhea group, and at this stage liver abscess often develops. The author states that transmission of the disease by flies is supposed to be rare, but viable amebæ have been found on the fly and in its intestinal tract. This insect may, therefore,

be a more common vector than has generally been thought. Amebiasis is undoubtedly common in the South and, also in some of its manifestations at least, is more frequent in the North than is generally recognized. The infestation is difficult of diagnosis, its detection requires a competent protozoologist.

**Angina Pectoris**—Chaille Jamison, after discussing the etiology and classification of cases of angina pectoris, emphasizes the importance of differentiating the various types of angina, and particularly the angina of coronary thrombosis, for the reason that the same treatment is not applicable to all forms of the affection. A grave mistake has been made in teaching that angina is a disease in which treatment is of no avail. As is well known, amyl nitrite by inhalation, or a nitroglycerin tablet under the tongue or hypodermically, will relieve attacks, and often thereby save life. The patient known to have angina pectoris should never be without one of these remedies, and should use them at the first intimation of trouble. The angina of effort in which there is evidence of exhaustion of the heart muscle, should be treated by at least four to six weeks' rest in bed, the administration of potassium iodide in as full dosage as the patient will tolerate, the eradication of foci of infection, and the elimination of tobacco. After the initial rest period the patient should be permitted to be up only a few hours a day; business should be pursued only during the morning hours, and an hour or two in the afternoon should be given to complete rest. When there is general arteriosclerosis, with hypertension and hypertrophy of the heart, in addition to the measures above advocated, a course of Nauheim baths, which can readily be given at home, is of distinct value, of even greater value when hypertension is marked is the twenty-minute hot bath followed by a rest of an hour or two. In the course of time patients of this type may be allowed limited exercise of a mild nature (walking or golf on level ground). Whiskey well diluted or light wine may be allowed. Where coronary disease is present (and it is present in the majority of cases) digitalis seems to do more harm than good. If there is evidence of accompanying failure of the right heart, then digitalis probably should be used, though the pain of angina usually disappears when frank heart failure sets in. Where syphilis is proved, antiluetic treatment should, of course, be instituted, but never intravenous medication. The treatment of the angina of decubitus does not materially differ from that of the angina of effort, except that greater diligence is necessary. Coronary thrombosis, during the immediate attack, should be treated by large doses of morphine by needle. When the attack has subsided, bed rest must be absolute, and an ice-cap

must be applied continuously to the pericardium. No definite rules for the use of digitalis can be formulated. The writer questions whether sympathectomy may not do more harm than good, as the pain is a protective process, warning the patient that he must rest.

**Twilight Sleep in Major Surgery with Scopolamine-Morphine and Scopolamine-Ephedrine**—F. Lubitz of Graz refers to cases especially of gastric ulcer and cancer in which, owing to some complication, general narcosis is contraindicated. Originally he employed the scopolamine-morphine combination, giving a first injection of both alkaloids two hours before operation, then a quarter hour later a second one of morphine alone followed in an hour by a third one of scopolamine alone. There was no fixed pattern, the aim being to individualize the method and dose for each case and give each in divided dose. The total amount given per operation was 3-100 gram of morphine and 1-1000 gram of scopolamine (roughly half a grain of morphine and 1-65 grain of scopolamine). Tested in 15 cases the method failed in 5 and presumably general narcosis was substituted although the author is silent on this point. Last December Kreitmair recommended a combination of scopolamine with ephedrine, an alkaloid obtained from *Ephedra vulgaris* which is closely allied to adrenalin. The claim was that the ephedrine virtually detoxicated scopolamine so that it could be given in larger doses with a superior narcotic effect. The author has now made trial of this association in 14 cases. From 20 to 30 decigrams of scopolamine are divided into ampoules with the addition of enough ephedrine hydrochloride to give each ampoule 1 mgm of scopolamine and 25 mgm of ephedrine, but the dose is divided as before into two to three separate injections, preceded also by two injections of morphine. The smallest total amount of scopolamine required was about 1-40 grain but the narcosis was complete and there were none of the drawbacks of ether narcosis such as vomiting and bronchitis. Ephedrine has been made by synthesis, but the author has tested only the natural product.—*Munchener medizinische Wochenschrift*, June 16, 1927.

**Typical Laboratory Infection with Asiatic Cholera**—Prof. A. Sata of Osaka speaks of the epidemic of cholera which reached some of the Japanese cities in 1925, having been brought in from Shanghai. In the following year there was no true epidemic but a few scattered cases occurred, none of them in Osaka. In December, 1926, Dr. Matsusaki of Osaka began some experiments with cultures of cholera vibrios and other pathogenic organisms. In January, after having worked incessantly day and night and be-

coming run down, he suddenly developed a persistent diarrhea, without griping but with vomiting and at once suspected an artificial infection with cholera. Dr. Kumagai, an authority, confirmed this diagnosis—a case of medium severity. The patient was isolated in the city institute for infectious diseases and through the incessant diarrhea and vomiting was brought very near death. He was treated with numerous intravenous injections of saline solution and glucose, with digalen and camphor, and passed the danger point on the third day, convalescing slowly. The cultures had been growing for a year and a half and the experiments had consisted apparently of pencilling them thinly on the natural skin, upon which they grew luxuriantly. Every precaution in use was taken to prevent contagion by the stomach and lungs. In the skin experiment it was decided that the vibrios could penetrate the intact skin and reach the lymph-nodes and blood, but it is not clear from the brief communication whether the patient and his colleagues made these experiments on themselves or merely on laboratory animals. This conclusion had evidently been reached as a result of experiment before the accidental inoculation of the patient. The same positive results were obtained with the typhoid bacillus and the dysentery bacillus.—*Deutsche medizinische Wochenschrift*, June 17, 1927.

**The False Leprosy (Punedos) of Guatemala**—R. Robles, a physician of Guatemala, gives a description of a virtually new and unplaced disease which occurs among the aborigines and whites of his country and which has for many years been confused with true leprosy. It is incurable, papillomatous, and tends to appear in successive outbreaks, there is also a foul odor about the patient which in any case would lead to his isolation or segregation. Nothing is known of the cause, but the malady appears in childhood in those heretofore healthy, the primary lesions showing in the feet as if some sort of insect had conveyed the malady, yet nothing like a bite or abrasion has ever been recognized. The early lesions are erythematous, circumscribed, red or livid in hue, and tender to touch and are first seen in the region of the instep, going higher or lower at times but always on the anterior surface. At the same time, the patient shows signs of a general infection, has general malaise, fever, prostration, headache, and joint pains, a picture not unlike that of grippe, with the alternative of a malarial infection. The attack passes off and some months later returns with more spots and an edema of the lower extremities which becomes in time chronic. The affected skin chaps and now papillomatous lesions are superposed. However the attack is self limited and another but shorter period of comparative

health sets in After several of these outbreaks the papillomatous feature, which has limited itself largely to the toes, becomes a source of deformity and disability, the digits being in time completely effaced Other portions of the foot may be involved but thus far no lesions outside the feet have been noted, with the exception of secondary inguinal adenopathy Extensive studies, some of which have been made by Noguchi, have failed to reveal any pathogenic agent—*Bulletin de l'Académie de Médecine de Paris*, June 7, 1927

**Forensic Cinematography**—Professor H. Matti of Berne refers first to the approved applications of cinematography to medicine and proposes to extend these in connection with damage suits, with particular reference to limitation of natural motion He has for some years been especially interested in the alleged crippling, following spondylitis, which includes so-called painful inhibition He has had numerous motion pictures made of these cases and has noted a marked discrepancy between the actual movements and the painful sensations of which the patients complained It is often desirable for the patient to be coached psychologically, in order that he may, if sincere, cooperate with the examiner, and often he takes the liveliest interest in the procedure It may be shown beautifully that an active muscular fixation of the spine may take place in simulators, aggravators, and neurotics Cinematograms of patients with actual rigidity of the spine which results from severe organic alterations are necessary for the control of the preceding It is of the greatest importance to take follow-up pictures of patients and compare them with the originals By taking several series of pictures it soon becomes apparent that simulation cannot be consistently kept up, whereas in an organic case constancy is seen The author does not set himself against the ordinary methods of the neurologist and makes it a rule to obtain testimony from both the neurologist and the orthopedist as a control of his pictorial method of exploration It is of course of great importance for therapeutic progress to follow up these cases pictorially but the author is interested here only in the forensic aspects of the procedure—*Schweizerische medizinische Wochenschrift*, June 4, 1927

**Clinical and Therapeutic Aspects of Influenza from 1889 to 1927, The Value of Salicin in Treatment**—E. B. Turner, writing in the *British Medical Journal*, July 16, 11, 3471, records his experience in the treatment of some 3,600 to 3,900 cases of influenza in the various epidemics, beginning with that of 1889 In combating this disease he has found salicin a most valuable

medicament During the severe epidemics of December, 1918, and March, 1919, he treated over 700 cases with salicin, and in the entire number had no complications, no bronchitis, no pneumonia, and not a single death The essentials of the salicin treatment consist in giving the drug as soon as there is a definite rise of temperature and keeping the patient warm in bed on light simple food Twenty grains of salicin are given every hour for the first twelve hours, then 20 grains every two hours for the next twelve hours, in many cases this is sufficient, but if not, the dose of 20 grains may be repeated from four to eight times a day, as may be necessary For young persons the dose is one grain for every year plus an extra grain Large and frequently repeated doses are necessary because the drug is eliminated with extreme rapidity Turner, in his thirty-eight years' experience found that no infection spread from anyone who commenced taking salicin as soon after the onset of the illness as it was possible to give it The sooner the treatment is begun the quicker do the symptoms subside The more acute the symptoms and the higher the temperature the more quickly does it yield to treatment When the temperature has dropped, before allowing the patient out of bed 60 drops of sal volatile are administered three or four times a day, if a tonic is required strychnine and nitroglycerin are given Salicin not only shortens the duration of the disease, but abolishes the numerous sequelæ The drug is not so rapidly effective in cases in which there is a treble or quadruple infection Many cases of catarrh and fever yield to this treatment, though it is not necessary to give the large doses of salicin so often In the prevention of influenza, Turner has found the army vaccine of mixed bacilli more effectual than that made from the supposed microbe of influenza

**The Pfeiffer Bacillus and the Pseudo-Pfeiffer Bacillus**—B. Trambusti of Genoa has recently made a special study of these organisms as such and apparently without any bearing on the allied question of the etiology of influenza The true Pfeiffer organism is especially toxigenic while the other is characterized especially by the production of aggressins The two agree well in their morphology and the mechanism of their pathogenic activities is similar The difference between the two which was first mentioned is related to differences in leucotropism, which is marked in the true organism and nearly absent in the false This behavior of the former is noted in all the highly toxic strains examined and likewise in the less virulent The leucocytes are able to destroy the true organism in a very short time—a few hours after its introduction into the animal economy, with production of certain endotoxins which are rapidly eliminated—*Lo Sperimentale*, June 10, 1927

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE PREVENTION OF OPHTHALMIA NEONATORUM

It is both the moral and the legal duty of the physician to use for the benefit of his patient the accepted results of scientific medical study. Not only must he possess "that reasonable degree of learning and skill that is ordinarily possessed by physicians and surgeons in the locality where he practices, and which is ordinarily regarded by those conversant with the employment as necessary to qualify him to engage in the business of practicing medicine and surgery,"—not only is it his duty to use reasonable care and diligence in the exercise of his skill and the application of his learning to accomplish the purpose for which he was employed, but as the Court of Appeals has declared "He is bound to keep abreast of the times, and a departure from approved methods in general use, if it injures the patient, will render him liable, however good his intentions may have been."

There are few fields of medical practice in which the necessity of keeping abreast of the times is more important than that of obstetrics.

For many years it has been the recognized practice to instill in the eyes of the new-born child immediately after delivery a one per cent solution of nitrate of silver or an equally effective agent in order to prevent the development of ophthalmia neonatorum.

In his authoritative work on the *Practice of Obstetrics*, J. Clifton Edgar declares that "As soon as the child is born its face must be carefully washed, special attention being given to the eyes, and even when infection is not suspected one or two drops of a 1 per cent silver-nitrate solution should be dropped into each conjunctival sac. This may be washed away in a moment or two with salt solution if desired. It has now become with most obstetricians in maternity service a matter of routine practice to use this 1 per cent solution in the eyes of all infants, and since the method was introduced the number of cases of ophthalmia neonatorum has decreased enormously. As an illustration, we may cite the experience of Cr  d  , who suggested the method. At his Lying-in-Asylum, at Leipsic, before the use of silver nitrate, this form of ophthalmia occurred in 108 per cent of all infants, after the treatment was systematically carried out the percentage fell to 0.1 or 0.2 per cent. Other similar experiences have been reported. The methods of procedure

will almost invariably cure or protect the infant from this infection, but we have the further duty of protecting nurses, relatives and physicians. It is hardly necessary to point out the extremely infectious character of the discharge from the eyes of a patient with gonorrheal ophthalmia or to emphasize the importance of avoiding the chance of infecting a clean eye."

So universally recognized did the use of this nitrate of silver solution become that on August 10, 1922, there was added to the Sanitary Code of the City of New York Section 201, which provides

"Precautions to be observed by physicians, nurses, midwives and other attendants for the prevention of ophthalmia neonatorum in the eyes of all new-born children. It shall be the duty of every physician, nurse, midwife or other person in attendance on a confinement case, to instill in the eyes of the new-born child, immediately after delivery, and before the expulsion of the after-birth, a one (1%) per cent solution of nitrate of silver or an equally effective agent in order to prevent the development of ophthalmia neonatorum in the eyes of all new-born children."

Further emphasizing the importance of this procedure, the Department of Health of the City of New York prepared "*Instructions to Midwives for the Care of the Eyes of New-Born Babies*" and arranged for the preparation and distribution of capsules containing a silver nitrate solution for use in obstetrical cases. In these instructions the Board of Health declared

"As soon as the baby is born, carefully clean the eyelids with water that has been boiled, using a fresh piece of soft linen cloth or clean absorbent cotton for each eye. Wipe the lids, from the nose outward, without opening the lids. Then the eyelids must be separated and three drops of a 1 per cent solution of silver nitrate dropped into each eye.

"The enclosed capsules each contain a sufficient quantity of the 1 per cent solution of silver nitrate for each case.

"Keep the capsules in a warm room for a while before using. If they are very cold they may break when squeezed."

Outside of the City of New York the State Department of Health has jurisdiction. The State Department established a Sanitary Code by

which the necessity for the use of nitrate of silver is likewise recognized. By Regulation 10 of Chapter 2 of that Code, added on February 7, 1922, it is provided

"Precautions to be observed for the prevention of ophthalmia neonatorum. It shall be the duty of the attending physician, midwife, nurse or other person in attendance on a confinement case to use at the time of the delivery prophylactic measures such as the instillation into both eyes of one per cent solution of nitrate of silver, or an equally efficient agent, to prevent ophthalmia neonatorum or the development of sore eyes in the infant due to infection at birth."

Under the authority of this regulation, the State Department of Health, through its Division of Laboratories, distributes a one per cent nitrate of silver solution, enough of the same being contained in a wax ampule, which together with printed directions for the use of the same are enclosed in a small wooden box. The printed instructions bear in part the following "1 per cent nitrate of silver solution for the care of the eyes of new born babies" and then follow directions for its use.

In a leaflet issued by the Division of Child Hygiene of the State Department of Health on the care of new born babies, the following in-

structions with respect to the care of the eyes are contained

"The eyes should be carefully cleansed with a saturated solution of boric acid, and into each eye the physician or nurse should put two or three drops of a one per cent solution of nitrate of silver to prevent sore eyes and possible blindness."

In addition to all these authorities we cite from Dr. Hobart A. Hare's work on *Practical Therapeutics* (18th ed.) where speaking of the use of nitrate of silver he says at p. 393.

"As a prophylactic for ophthalmia neonatorum it is invaluable, and in most cases a 1 per cent solution is adequate. If infection is present, 2 per cent should be used."

So universally recognized has the use of silver of nitrate solution or other equally effective agent in the care of infants' eyes become that it is obviously with no thought of presenting anything new to the profession that this article is written, but rather to call attention to the principle of law that requires the physician "to keep abreast of the times, and a departure from approved methods in general use, if it injures the patient, will render him liable, however good his intentions may have been."

---

## STILL BIRTH CLAIMED DUE TO QUININE AND MORPHINE

In an action against a physician the complaint charged that he was engaged in August to attend the plaintiff and to take care of her during the period of her pregnancy and deliver her of her then unborn child, that in October, immediately preceding the plaintiff's confinement the defendant did not use reasonable care or skill in the first stages of labor but unskillfully and negligently during that period administered 20 grains of quinine to the plaintiff and then permitted her to remain unattended for a period of approximately eight hours, that he further negligently administered a hypodermic of morphine when labor pains were in progress and again left the patient unattended, and that he further failed and neglected to administer a proper cleansing of the patient after her delivery, that by reason of these acts of alleged negligence upon the part of the defendant physician it is claimed that the plaintiff's child was born dead and that she suffered bodily and mental pain and anguish and also incurred expenses for medical and surgical care and medicines. Plaintiff asked for \$25,000.00 damages.

The plaintiff had been a patient of the defend-

ant for several years, and during her period of pregnancy had been under the defendant's care, being given the necessary examinations and advice during the prenatal period.

On October 16th, at about 2 A. M., the patient by telephone advised the defendant that she was having pains. He advised her to enter the hospital where she had made reservations. At about 9:30 A. M. he visited her at the hospital. The pains were weak and infrequent and an examination revealed a live foetus. There was no engagement of the head and the cervix was but one finger dilated. He saw her again at about 4 P. M. on the same day at which time the pains were stronger and more regular. At this time he ordered a nurse to administer 20 grains of quinine and one ounce of castor oil. Examination made at this time disclosed that the head was engaged but the cervix was still only one finger dilated. He saw her again at 9 P. M. of the same day, her pains were stronger but not severe, and there being no unfavorable reaction from the previous administration of quinine, twenty grains more were ordered administered. At midnight of October 16th she was having regular severe pains.

and was in active labor, examination disclosed two fingers dilation

The defendant had returned to his office, and at about 2 A. M., October 17th, the supervising nurse, over the telephone, advised that the patient was having strong, regular pains and that the cervix was dilated about  $2\frac{1}{2}$  fingers. The defendant then ordered morphine sulphate grains  $\frac{1}{4}$ , atropine sulphate grains  $\frac{1}{150}$  if pains became unbearable, and told the nurse to call him again within a few hours. At 4 A. M., October 17th, the nurse telephoned that the patient's pains were strong and very regular, that she was about three fingers dilated and was complaining on account of her pain. At 6 A. M. of that morning the defendant was advised that the patient was ready for delivery and was having very severe pains. The physician reached the hospital at about 6 20 A. M. and on examination found that the patient was from  $3\frac{1}{2}$  to 4 fingers dilated, fetal heart sounds were heard and the patient's condition was good. She was, however, complaining of the pains and requesting an anaesthesia. Under the defendant's direction the patient was given a whiff of ether to relieve the severity of the pains, and an anaesthetist was called. The anaesthetist arrived at about 7 A. M. At that time the cervix was completely dilated and the fetal heart sounds were heard by both the defendant and the anaesthetist. The head was low down. Gas oxygen was administered and patient was also given 3 m. of pituitrin

hypodermically. At 7 20 A. M. she gave birth to a still born female. The cord was pulseless and artificial respiration was resorted to. On squeezing the chest and lungs during the artificial respiration a large amount of yellow and brown fluid was expelled from the infant. The defendant and the anaesthetist continued to work over the baby for about two hours without being successful. The defendant ascribed the cause of the death of the baby to premature respiration (fetal) while in uterus, causing inspiration of amniotic fluid and asphyxia.

The plaintiff remained at the hospital for about ten days and made an uneventful recovery. During her stay at the hospital she had accepted the loss of her baby philosophically and did not blame the defendant. After she had been home two days the defendant visited her, at which time she became abusive and charged the defendant with being responsible for the death of the child. When the defendant called at the patient's home a few days later he was told that the patient was not in. This was the last that he had seen or heard of the patient until this action was instituted against him. She refused to pay defendant for his services and when he instituted an action to collect for the same he was met with a malpractice action against him. This action was never pressed for trial by the plaintiff and was eventually discontinued, terminating the matter favorably to the defendant.

### UTERINE BLEEDING—CLAIMED ABORTION

In this action it was charged that the defendant physician had been engaged on the 15th of December to attend the plaintiff and that he treated her from time to time until the 17th of the following March, that he failed to exercise the proper care and skill in his treatment and that by reason of his improper treatment the patient's health and constitution were injured and she was obliged to expend large sums of money in an attempt to be cured of the injuries caused by the physician's negligence.

About the beginning of November the patient had called at the physician's office complaining of pains in the pelvic region and upon examination she was found to be suffering from an inflamed cervix. At this time he painted the inflamed area with a solution of silver nitrate and packed her with gauze. When she returned on the following day the physician found that the packing had been removed and that she had had uterine bleeding. Another physician was then called in who

took charge of the patient and packed her with sterile gauze. She subsequently returned to the office of the first physician who says that the patient stated to him that she was pregnant and requested that he abort her which he refused to do and refused to either attend or treat her. That he saw or heard nothing further of the patient until this action was instituted against him.

The physician who had been called in consultation about six months later was called to the plaintiff's home and upon his arrival he found her in bed and she exhibited to him a dead fetus of about five months and asked that this physician attend and treat her. This physician likewise refused to attend and treat the plaintiff or to give her a death certificate of the fetus. The next he heard from the patient was the institution of a suit against him.

The plaintiff failing to prosecute the action, on motion of the defendants the same was dismissed for lack of prosecution.

# NEWS NOTES

## THE CATTARAUGUS COUNTY MEDICAL SOCIETY

A special meeting of the Cattaraugus County Medical Society was held on August 4, 1927, in the Olean House, Olean, N. Y., to consider the report of the Committee on Public Health and Public Relations of the Cattaraugus County Medical Society. This report was as follows:

To the Cattaraugus County Medical Society:

Your Committee on Public Health and Public Relations has requested your Secretary to call this special meeting for the purpose of considering public health in this County, a matter which is of vital importance to the physicians and the citizens in general.

For the past four and one-half years there has existed in Cattaraugus County a county Board of Health, created by the Board of Supervisors to make possible participation by the county in the Rural Health Demonstration of the Milbank Memorial Fund. The Milbank Memorial Fund, and its agent, the State Charities Aid Association, following the creation of the county Board of Health, entered into some form of agreement with the county to supply, for a period of five years, part of the funds necessary for the activities which the Board of Health would undertake. It also offered its services in the determination of the various activities, and the amounts to be expended for each activity.

The period of five years, for which this agreement runs, expires at the end of this year. Judging from correspondence received from the Milbank Memorial Fund by physicians and others in the county, it has become apparent that the Milbank Fund is quite desirous of extending the period of its demonstration in this county. Within the past two weeks the newspapers have reported an action by the City Council of Salamanca, endorsing the Demonstration and requesting its continuation. We are informed that the Executive Committee of the County Tuberculosis and Public Health Association has before it at this time a similar proposal.

As yet the Medical Society itself has not been approached, nor has its approval as an organization been solicited.

However, your Committee has considered the advisability of determining the feeling of the physicians of the county, and more particularly the members of the County Medical Society, relative to an endorsement by the Medical Society of the continuation of the Demonstration.

The essential relationship of the practicing physician to public health, and his particular fit-

ness to judge its benefits, its efficiency, and its worth, make it important that his opinion in regard to the particular plan of public health work in existence in this county, be made available at this time, when a consideration is being given to its continuation and extension.

We have felt that this opinion might be of value and assistance to the officials of the county, the members of the county Board of Health, and the staff of the Milbank Memorial Fund and State Charities Aid Association.

The efficiency of questionnaires in the accumulation of frank opinions is well known. Your Committee, after mature deliberation, determined to send to each physician in the county, whether a member of the Society or not, a clear cut and concise questionnaire, dealing with the Demonstration. This has been done. It is for a consideration of the data so obtained, and for appropriate action thereon, that this meeting is being held tonight.

Briefly, the manner of procedure in the questionnaire was as follows:

Questionnaires were prepared containing questions with which you are already familiar. Each question was stated in such a way that the answer would be brief and definite. After the preparation of the questionnaires, 64 copies were signed and sealed by a notary. The cards sent to non-members were signed by the notary in red ink, and those sent to members, in blue-black ink. With this exception there was no mark of identification on the cards.

The names and addresses of the physicians were then carefully checked by a clerk, and the 64 copies were mailed by the notary and an assistant to the 64 practicing physicians in the county.

A notation on each questionnaire stated that the physician's signature was not necessary. This was thought advisable, in order to obtain the fullest and frankest opinion.

Of the 64 questionnaires sent out, 52 have been returned. When the questionnaires were received they were checked by the notary, and identified as the questionnaires sent out. It was necessary to send out three additional questionnaires, two physicians losing theirs, and one having made mistakes in filling his out.

Following the checking of the returned questionnaires, a summary was made by the notary, of the answers. This summary is hereby submitted.

Total number of questionnaires sent out 64  
Total number returned 52

Number received from non-members (red signature) 10  
 Number received from members (blue-black) 42  
 Of the 52 cards received, 18 were from local health officers

## SUMMARY OF ANSWERS

## Question No 1

In the event that the present Health Demonstration were to consider remaining in this County for another 5 years, would you favor the County Medical Society endorsing and requesting such a move?

Answered "yes" non-members 2, members 10, total 12  
 Answered "no" non-members 8, members 30, total 38  
 Indefinite answers 2

## Question No 2

In the event that the Demonstration withdraws at the end of this year would you favor the continuation of the County Board of Health?

Answered "yes" non-members 5, members 22, total 27  
 Answered "no" non-members 5, members 18, total 23  
 Indefinite answers 2

## Question No 3

Do you approve of the County Health Unit idea as developed and demonstrated in this County?

Answered "yes" non-members 4, members 15, total 19  
 Answered "no" non-members 6, members 23, total 29  
 Indefinite answers 4

## Question No 4

Do you favor the cooperation of lay and unofficial bodies (such as the Milbank Fund and the State Charities Aid Ass'n) in the official health work of this County?

Answered "yes" non-members 3, members 9, total 12  
 Answered "no" non-members 7, members 32, total 39  
 Indefinite answer 1

## Question No 5

Has the present Health Demonstration affected your practice?

Answered "none at all" 26  
 Answered "favorably" 12  
 Answered "adversely" 11  
 Indefinite answer 3

## Question No 6

Do you believe that the present Demonstration is having a pauperizing effect on the people of the County?

Answered "yes" 35  
 Answered "no" 14  
 Indefinite 3

## Question No 7

Do you think that the present Demonstration has increased or lessened respect for the practicing physician in the County?

Answered "increased" 12  
 Answered "lessened" 32  
 Indefinite answer 8

## Question No 8

What part or parts of the work of the present Demonstration do you think have proved of most value?

Tuberculosis work 39  
 Laboratory 39  
 Venereal disease clinics 26  
 Health, education and publicity 16  
 Sanitation 11  
 Nursing 11  
 Infancy, maternity and child hygiene 9  
 Communicable disease control 4

## Question No 9

What age group are you in?

20 to 40 years 14 40 to 60 years 25  
 Over 60 years 12 not answered 1

## Question No 10

Are you a local health officer?

Yes 18 No 34

## Question No 11

Do you think that the people of the County have had "value received" for the County's expenditures in the County Board of Health?

Answered "yes" non-members 3, members 12, total 15  
 Answered "no" non-members 6, members 28, total 34  
 Indefinite answers 3

It is evident from a study of the above answers that 52 out of 64 physicians, or over 81% of the physicians, thought the questionnaire deserved consideration

It is evident also, that 38 physicians in this county, much more than half of the total number in the county, definitely do not want to see the present demonstration continue. Only 12 are definitely in favor of its continuation

In the event that the demonstration withdraws at the end of the present year 27 physicians would like to see the county Board of Health continue, but only 18 would have it continue in the way it has been developed and demonstrated so far

Only 12 physicians in the county record themselves as favoring the entrance of lay and unofficial bodies such as the Milbank Fund and the State Charities Aid Association into the health work of this county

In answer to the oft repeated assertion that the demonstration is helping the physician, 26 answer that they have experienced no such effect, and 11 report an adverse effect

That the present demonstration is pauperizing the public is stated definitely by 35 doctors, and it is interesting to note, in a study of the questionnaire cards, that one of the physicians recording himself as favoring the demonstration, nevertheless reports this tendency

It is an undisputed fact that the backbone of all effective public health endeavor is the family physician, yet 32 physicians record themselves

as believing that the present demonstration is lessening respect for the practicing physician

A study of the answers brings out likewise the fact that these opinions are held by non-members of the Society to as great an extent as by members

Tuberculosis work, the laboratory, and venereal disease clinics meet with much more approval from the physicians than the other branches of the work, with communicable disease control, infancy, maternity and child hygiene, and public health nursing, as they have been conducted in this county, meeting with very little approval. Those activities which have been successful are those which have been proved elsewhere, are not experimental, and not subject to unofficial interference

A study of the answers, tabulated by age groups of those answering, shows that opposition to the demonstration is not confined to the older men, but is just as acute in the younger group

To the question as to whether the county has had its money's worth, for the money the county itself has expended, 34 physicians give "no" as their opinion. The opinion of the physicians on this question is one which is of great interest due to their peculiar and fitting position to judge. No expert, no matter how competent, and regardless of where he is from, can, in a few days' study of the situation here, form an opinion as valuable as that expressed by 34 physicians who have seen the demonstration at first hand, and clearly, for nearly five years

Your Committee is of the opinion, after a careful study of the questionnaires, and after conference with medical men in this county, that the Cattaraugus County Medical Society should go on record as opposing a continuation of the present health demonstration after the end of the present year. We feel that five years of the Milbank Demonstration has demonstrated little that affects this county favorably, and it is in this county that we are interested. Rather has the Demonstration demonstrated that, wherever lay bodies have attempted to interfere with and guide official health work, the result has been inefficiency and chaos. We, therefore, wish the Society to put itself on record as favoring a county Board of Health, but not the type of county board of health that Cattaraugus County has experienced during the past four and one-half years. We wish to record ourselves as favoring separate municipal health departments in the two cities of the county. We wish the Society to put itself on record as favoring and pledging its support to official health workers, not guided by the whims and fads of at times inexpert lay experts. To quote the words of a writer in the July 2, 1927, issue of the *Journal of the American Medical Association*

"We have every confidence in all those

specialists in public health who are legitimately specialists. We have a quite natural suspicion of those lawyers, politicians, business men, preachers, and otherwise unoccupied ladies, grouped so loosely and thoughtlessly as "social workers" who have not had basic training or understanding of those subjects to which we have so seriously and with single hearted zeal devoted our whole preparation and life"

And further quoting the same writer

"We are back of every sensible measure of accredited preventive medicine. We are more than willing to play our essential part in the program of public medicine. We are not, however, a class prone to accept without due consideration the vaporings of every volunteer amateur Moses"

We wish the Society to oppose any tendency to build up in this county an expensive and unwieldy health machine. We feel that there are limits to the amount of money that can be spent with profit for public health, and limits to the numbers in personnel which a county of this size should support. We feel that the farmers of this county, whom we recognize as its backbone, should not be asked to support the large number of public health nurses which they now, through state and county taxes, are supporting. We feel that public health work, like other public works, is ruled by a law of diminishing returns, and that increasing expenditures are not necessarily followed by corresponding increasing returns

We further feel that the County Medical Society should frown on efforts on the part of any organization to inject politics and political considerations into the public health situation in this county

We, the members of your Committee, feel that there has been a good deal of propaganda dealing with "experts" and "expertness" which has reflected on the county, its people, and its medical men

We feel that a good public health nurse must be primarily a good general nurse, and a good public health official primarily a good practitioner. One must first have experience in the disease, before one can effectively and with co-operation practice prevention

We resent also the continuous campaign of glorification which has been a part of the present demonstration. We can see no more reason for such a campaign of praise of the workers of the county Board of Health than there is for similar adulation of any other officials of the county or the cities who are doing their duty, and we resent the efforts of interested persons to exploit the profession in which we are engaged

We disapprove of premature and overenthusiastic reports in general. We resent in particular reports reflecting directly or indirectly,

Number received from non-members (red signature) 10  
 Number received from members (blue-black) 42

Of the 52 cards received, 18 were from local health officers

### SUMMARY OF ANSWERS

#### Question No 1

In the event that the present Health Demonstration were to consider remaining in this County for another 5 years, would you favor the County Medical Society endorsing and requesting such a move?

Answered "yes" non-members 2, members 10, total 12  
 Answered "no" non-members 8, members 30, total 38  
 Indefinite answers 2

#### Question No 2

In the event that the Demonstration withdraws at the end of this year would you favor the continuation of the County Board of Health?

Answered "yes" non-members 5, members 22, total 27  
 Answered "no" non-members 5, members 18, total 23  
 Indefinite answers 2

#### Question No 3

Do you approve of the County Health Unit idea as developed and demonstrated in this County?

Answered "yes" non-members 4, members 15, total 19  
 Answered "no" non-members 6, members 23, total 29  
 Indefinite answers 4

#### Question No 4

Do you favor the cooperation of lay and unofficial bodies (such as the Milbank Fund and the State Charities Aid Ass'n) in the official health work of this County?

Answered "yes" non-members 3, members 9, total 12  
 Answered "no" non-members 7, members 32, total 39  
 Indefinite answer 1

#### Question No 5

Has the present Health Demonstration affected your practice?

Answered "none at all" 26  
 Answered "favorably" 12  
 Answered "adversely" 11  
 Indefinite answer 3

#### Question No 6

Do you believe that the present Demonstration is having a pauperizing effect on the people of the County?

Answered "yes" 35  
 Answered "no" 14  
 Indefinite 3

#### Question No 7

Do you think that the present Demonstration has increased or lessened respect for the practicing physician in the County?

Answered "increased" 12  
 Answered "lessened" 32  
 Indefinite answer 8

#### Question No 8

What part or parts of the work of the present Demonstration do you think have proved of most value?

Tuberculosis work	39
Laboratory	39
Venereal disease clinics	26
Health, education and publicity	16
Sanitation	11
Nursing	11
Infancy, maternity and child hygiene	9
Communicable disease control	4

#### Question No 9

What age group are you in?

20 to 40 years	14	40 to 60 years	25
Over 60 years	12	not answered	1

#### Question No 10

Are you a local health officer?

Yes	18	No	34
-----	----	----	----

#### Question No 11

Do you think that the people of the County have had "value received" for the County's expenditures in the County Board of Health?

Answered "yes" non-members 3, members 12, total 15  
 Answered "no" non-members 6, members 28, total 34  
 Indefinite answers 3

It is evident from a study of the above answers that 52 out of 64 physicians, or over 81% of the physicians, thought the questionnaire deserved consideration

It is evident also, that 38 physicians in this county, much more than half of the total number in the county, definitely do not want to see the present demonstration continue. Only 12 are definitely in favor of its continuation

In the event that the demonstration withdraws at the end of the present year 27 physicians would like to see the county Board of Health continue, but only 18 would have it continue in the way it has been developed and demonstrated so far

Only 12 physicians in the county record themselves as favoring the entrance of lay and unofficial bodies such as the Milbank Fund and the State Charities Aid Association into the health work of this county

In answer to the oft repeated assertion that the demonstration is helping the physician, 26 answer that they have experienced no such effect, and 11 report an adverse effect

That the present demonstration is pauperizing the public is stated definitely by 35 doctors, and it is interesting to note, in a study of the questionnaire cards, that one of the physicians recording himself as favoring the demonstration, nevertheless reports this tendency

It is an undisputed fact that the backbone of all effective public health endeavor is the family physician, yet 32 physicians record themselves

## MEDICAL WARES

### RADON SEEDS

Radium has been used in therapeutics since its discovery in 1898 by Madam Curie. It has also served to unlock the secrets of the constitution of the atom, and to explain the ultimate composition of matter. Every practicing physician has a deep interest in radium, for it is one of the trinity of measures used in the effective treatment of cancer—surgery, the  $\gamma$ -ray, and radium. Each of these forms of treatment has been standardized, and the means of their application have been made available to every physician.

It is a general principle in the treatment of cancer that the order of choice of the three methods shall be as follows:

1. Surgery for the complete removal of the new growth.

2. The  $\gamma$ -ray for growths on the surface which can be readily removed.

3. Radium for deep growths.

Radium is enormously expensive—about \$70,000 per gram. It was produced first in Europe from ores containing only a small per cent of uranium. Then large deposits containing a very considerable quantity of uranium were discovered in Colorado. The Belgians later discovered a higher grade of ore in Africa, and now the principal source of supply of radium is Belgium. However, the amount of radium that the world needs is much less than that which was at first supposed, because the standard means of applying radium is to collect its “emanation” in tubes which are sent to a doctor in exact doses. Since it is the active deposit from the emanation which is the therapeutic agent, the radium itself is kept in a lead box from which its emanation is pumped off as it is needed. A few grams of radium is therefore sufficient to treat a number of persons at one time.

The peculiar property of radium is that it breaks down into a series of other elements like a stream of water flowing down a series of cascades or rapids, the final element of its transformation being lead. While nearly all the disintegration products are solids, one is a gas called *Radon*. This gas or emanation is used in therapeutics, because its decay products are the same as those from radium.

Radon is used in the form of small sealed tubes, called *Radon Seeds*. A solution of radium promide in water containing hydrochloric acid is placed in a box of lead. The gas from this box is pumped out once or twice a day and is purified by the removal of its air, water, hydrochloric acid and other undesirable products. It

is then sealed in tubes of glass, platinum, gold, or other material, which are then ready for application to the surface of the body, or for insertion into a tumor. This method of applying radium was first discovered in 1913, but in recent years it has been developed on a commercial scale, and has been brought within the reach of every physician.

Commercial radon tubes are usually from 3 to 10 millimeters long, and about one half a millimeter in diameter.

In order to comprehend the dosage of radon or radium, one must know something about the newer conception of the composition of matter. An atom is composed of particles of positive charge, around which particles of negative charge (electrons) revolve at distances which are very great compared with the diameters of the particles. An atom of hydrogen consists of one positively charged particle, and one negatively charged particle. The other elementary substances form a series containing an increasing number of particles of both kinds of electricity until the limit of the number of particles is reached in radium and uranium. The number of charged particles and the complexity of their arrangements in the atom of radium are so great that the atom is somewhat unstable, and continually gives off particles of electricity, both positive and negative, with the result that radium itself slowly changes its nature, producing other elements, the last one of the series being lead.

The negative particles flying off from the atom with a speed almost as great as that of light, give rise to vibrations which are analogous to those of light or the  $\gamma$ -ray.

There are therefore three radiations from radium: 1. Particles of positive charge, called *Alpha Rays*, 2. Particles of negative charge, called *Beta Rays*, 3. Electro-magnetic waves, called *Gamma Rays*.

The gamma rays are similar to the  $\gamma$ -rays, and are the ones which have the principal therapeutic effects. The alpha and beta rays are largely undesirable, but the greater proportion of them may be excluded by a thin sheet of glass or metal. The thickness of the glass, gold, or platinum out of which radon seeds are made, is adjusted to permit the passage of a definite amount of alpha or beta rays, while allowing practically all the gamma rays to pass out.

The intensity of radiation given off by a radon seed is expressed in *Millicuries*, one of which is the amount which is constantly given off by a milligram of radium. This definition is by no

purposely or otherwise, on the practicing physician. We feel that the Demonstration has no monopoly on philanthropy. Physicians in this county year after year unostentatiously do a vast amount of progressive preventive medicine. They did so before the arrival of the Demonstration, and they will do so after its departure.

Your Committee therefore, moves the adoption of the following resolutions:

*Resolved* that the Cattaraugus County Medical Society go on record as desiring the withdrawal of the Milbank Demonstration from this county, and opposing any request for its continuation after the termination of this year.

*Further resolved* that the Cattaraugus County Medical Society go on record as favoring and supporting a county board of health, conducted on a modest and practical scale, and

operated without interference from the State Charities Aid Association or other unofficial bodies.

*Further resolved* that the Cattaraugus County Medical Society, while expressing its appreciation to the Milbank Memorial Fund for its Cattaraugus County effort, records its opinion that this experiment has demonstrated the ineptitude of lay bodies to bring about properly the transfer of the theoretical to the practical.

*Further resolved* that a copy of this report be sent to the Committee on Public Relations of the New York State Medical Society, and that a copy of the minutes of this meeting be sent to our State Medical Journal.

The motion was carried, the vote being yeas 26, nays 5.

### THE CATTARAUGUS COUNTY "BULLETIN"

The Cattaraugus County Medical Society has issued its Bulletin number 2, dated August 20, 1927. It gives the resolution passed on August 4, at the special meeting of the Society, and continues:

"A complete report of the action of the society at this meeting, together with a verbatim copy of the report of the Committee on Public Health and Public Relations, is in process of printing, and will be mailed to each physician in the county within a few days."

*"Important"* Your Committee on Public Health and Public Relations is at present hard at work on a comprehensive program of sound and economical public health work for this county. The Committee will make a report at the next meeting of the Society. But, in the

meantime, the Committee wants suggestions from every physician in the county. Please send yours in."

"Do you read the Salamanca 'Republican-Press'? If not, why not? Sometimes on the same pages with advertisements for chiropractors and kidney pills, one finds copious adulation of the health demonstration, and unkind remarks about the Medical Society. One physician wrote a letter to this paper defending somewhat the health demonstration, and the end of his letter was placed to the right and slightly above the ad which read 'Kidney Trouble Cured'. Dr. Nelson has given me a course of adjustments. R. F. Nelson, Health Service."

### THE ALLEGANY COUNTY MEDICAL SOCIETY

The Allegany County Medical Society held its mid-summer meeting on Thursday, July 28, at the Hotel Joyce, Andover, with the president, Dr. H. E. Cooley, presiding and twelve members present.

The following Committee on Public Health and Public Relations was appointed: Dr. L. C. Lewis, Belmont, Chairman; Dr. N. H. Fuller, of Friendship; and Dr. F. E. Comstock, Wellsville.

Dr. Sadlier, President of the Medical Society

of the State of New York, addressed the meeting on the standards and activities of a county medical society.

Dr. Archibald E. Dean, District State Health Officer, discussed the relation of the Board of Supervisors to Public Health Nursing.

The scientific part of the program consisted of a paper on "Some Original Blood Pressure Observations," by Dr. Virgil C. Kinney, Superintendent of the Wellsville Sanitarium.

# THE DAILY PRESS

## ELECTRONS IN COMMON THOUGHT

The conception of electrons has penetrated into the common thought of the people to such an extent that an editorial writer, in the *New York Herald Tribune* of August 18, uses it in describing how electrons, racing from New York, lighted the great Jefferson searchlight in Charlottesville, Virginia. The writer says

"Their job began with the thought in Miss Gibboney's brain when the button of the flashlight was to be pressed. Electrons carried this thought message down the nerves to the muscles that did the pressing. Other electrons inside the fibers of these muscles forced the motion. When the switch of the flashlight was closed, still other electrons leaped by millions between the bits of brass that came in contact, flowed through the small wire of the lamp and heated it.

"Then came the first part of the race in which electrons were not the runners. The ray from the lamp was a light ray. Whatever light may be, it is not electrons. But the selenium cell on the small statue which the flashlight illuminated used electrons again. Each atom of this selenium contains thirty-four movable electrons. Two or three of these are rather loose. The light ray from the flashlight knocked out a few billion of these

Thus a feeble electric current was made through the selenium device. Then the electron relay race began. Those knocked out of the selenium flowed through a wire and passed the impulse to other electrons in a device called, quite appropriately, a relay. These new electrons took up the baton and passed it to an enormous army of their fellows waiting all along the miles of wire between New York and Virginia.

"Finally the impulse reached Charlottesville. There waited another team of electrons to carry it to the power circuit supplying the searchlight. This power also was electrons, a vast assemblage of them, that rushed across between the carbons of the great arc lamp, generating the light ray visible fifteen miles away. The Westinghouse engineers who arranged all this may not have thought of themselves as race promoters, but that is what they were. It was a race by the smallest and fastest runners in the world, for billions of electrons can stand like mediæval angels on the point of a needle, and the whole race, from Miss Gibboney's brain to the searchlight beam of Monticello, probably took no longer than a hundredth of a second."

## DYES AS GERMICIDES

The daily newspapers are spreaders of medical knowledge to an extent that few readers are aware, unless they watch for health items. The *New York Herald Tribune*, for August 30, discusses the effects of dyes on bacteria in the body in an editorial which is a model of popular scientific writing. The following extracts reveal the style of the writer.

"To the average sick man it probably is not a matter of grave concern whether the bacteria which inhabit him are dyed pale pink or bright purple, but it seems to matter hugely to the germs. This is the implication of the discussion on dyes as medicinal agents which Professor Hugh H. Young, of Johns Hopkins University, expects to open this week at the meeting of the American Chemical Society at Detroit. The use of dyestuffs to color the interior of the body as well as its habiliments is one of the newest phases of the science of chemotherapy.

"The value of a dye in medicine appears to be that it seizes hold of the bacteria against which it is directed and holds fast to those tiny creatures until it poisons them or otherwise incommodes

them into dying. No one knows just why the dyed germs decline to live. Perhaps they catch sight of their newly-decorated features and expire from shock.

"Old-fashioned germicides like carbolic acid or corrosive sublimate are too successful as poisons. Not only do they kill any unwary germs, but they also do enormous damage to the healthy living cells of the body. Sometimes this is inevitable: some of the healthy cells may have to be sacrificed to repel the germ invaders, as the general of an army may throw away troops of his own to help keep an enemy out. But it is better, if possible, to kill the germ and to let the body cell live. This, it is hoped, is where the new multi-covered germicides will find their best use. As some dyes are fast on wool but refuse to attach themselves at all to silk or cotton, so it is found that there are some which delight to color up bacteria but leave the body cells severely alone. It is this selective attack, not the accident of turning germs mauve or cerise, that gives the new dye therapy its place."

means scientifically correct, but it will enable a physician to visualize the strength of the radiations indicated by a radon seed. A millicurie of radon gives off the same energy as a milligram of radium in unit time.

The dosage of radium which a physician wishes to prescribe is expressed in *millicurie hours*. One millicurie of radon applied to a tumor for 100 hours gives off the same amount of radiation as 100 millicuries applied for one hour. Each package of radon seeds is marked with the millicurie content of emanation, so that a physician who buys the seeds gets the equivalent of a known quantity of radium.

The emanation contained in a radon seed is evanescent in comparison with that of radium. A period of 1,700 years will elapse before the rate of the emission of the emanation of radium is reduced to one-half its original rate. Radon loses one-half of its emanation in 3.85 days, and one-half the remainder in 3.85 more days. A radon seed left in the tissues for two weeks has exhausted 90 per cent of its strength. Radon seeds therefore soon become inert, and may not need to be removed from the tissues, except that they are foreign bodies.

The strength of the radiation from a radon seed and from all other radio-active substances, is estimated by means of an *electroscope*. An electroscope is an instrument of marvellous simplicity when its great delicacy and accuracy is considered. It consists of a piece of gold leaf about 1/16 inch wide and two inches long, one end of which is attached to an upright, insulated metal rod about the size of a lead pencil, so that the leaf hangs down beside the rod. The gold leaf and rod are enclosed in a case containing a window through which the gold leaf may be observed.

The observer charges the rod with frictional electricity by rubbing a piece of glass or sealing wax and touching it to the projecting part of the rod of the electroscope. The electricity causes the gold leaf to be repelled from the rod and to stand out at an angle from it.

When a radio-active substance is brought near the electroscope, the rays discharge the electricity and the gold leaf falls toward the rod. The rate of the fall as shown on a scale indicates the radio-activity of the substance that is tested.

Radon is applied by insertion into cavities of the body, such as the cervical canal, or by its implantation into the tissues by special applicators resembling small trochars. If a seed is to be left in place for only a short time, a thread is attached to it so that it may be removed. When an ulcerative effect is desired, the tubes come away when the tissues break down, but they may often be left in the tissues indefinitely without harm.

The dosage and distribution of radium implanted in a diseased tissue on a scientific basis requires considerable knowledge and experience. It is a general rule that one implant is required for every cubic centimeter of tissue. The size and shape of the tumor must therefore be known, and the extent of its ramification. One must also consider the effects of the radiation, and the pain, and inflammation, and destruction which it causes. Tables for the application of radon are published by the manufacturers, and professional advice is supplied to inquiring physicians. The manufacturers of the seeds supply a standard product whose potency may be compared to that of strychnine. A physician who buys strychnine in tablet form is supposed to understand its dosage and to use it with skill so as to secure effective results, and avoid its poisonous effects. The manufacturers of radon enable a physician to secure the effect of \$100,000 worth of radium at the price of one-twentieth of one per cent of its value.

Radium is also used for producing phosphorescence on a commercial scale. When zinc sulphide is exposed to the sunlight, it glows with a greenish light which persists for a few moments when it is placed in a dark place. Radium mixed with the zinc sulphide also causes the substance to glow, and to give off light continually. The activated sulphide is made into paint and is spread on the dials of clocks and watches. A few cents worth of radium will activate sufficient zinc sulphide to coat several dials.

Luminous paint was formerly made from mesothorium, which is a radio-active element derived principally from the waste material of Welsbach gas mantles, but very little is now produced on a commercial scale. Much of the activity of the mesothorium formerly produced was due to the radium which was always associated with it.

PRESCRIBED BY PHYSICIANS FOR MORE THAN 50 YEARS

when the system balks at  
ordinary foods—prescribe

# Maltine

P L A I N

ONE of the doctor's most common problems is to keep the patient properly nourished. Frequently the weakened and disorganized gastric system refuses to receive or assimilate the food which the body so urgently needs.

In such cases Maltine becomes a valuable aid to the physician. For this concentrated and palatable malt extract is not only an admirable food in itself, but *an agent for the assimilation of other foods*. The vitamins, mineral salts and soluble vegetable albuminoids which it contains are essential to body building.

In addition, tests show it to be rich in diastase—the active digestive agent which converts starch into sugar.

The essential proteid elements of *three* cereals—barley, wheat and oats—are present in concentrated form in Maltine, *and in Maltine only*. It mixes readily with milk, gruel, and similar foods, making them more palatable. It is uniformly pure, always obtainable, unfaillingly effective.

As a nutrient, as a digestant—give Maltine, the standard product of a standard house. Every druggist has it.

*Rich in diastase*

# OUR NEIGHBORS

## THE DANGER OF INTRA-NASAL ADMINISTRATION OF OILS

The danger of exciting a fatal pneumonia in infants by the inhalation of baby powders is well known to physicians. It is not so widely known that oils given intra-nasally may also cause death. This fact is developed in an editorial comment in the May 26th issue of the *Boston Medical and Surgical Journal*, which says

"One of the therapeutic measures in common use is the instillation of a few drops of oil into the nostrils of infants suffering from various conditions which give rise to congestion of the mucosa or to nasal discharge. Evidence has been accumulating to prove that this is not an entirely safe procedure. Recently Pinkerton (Pinkerton, H. *Am Jour Dis Chil*, 1927, vol xxxiii, pp 259-285) has published the results of a careful study of the behavior of oils aspirated into the lungs of infants, based on six autopsied cases in which the aspiration of oil was the underlying cause of death. The oily material encountered in several cases was identified as that administered as nose drops. In one the oil, through the history and typical color reactions in sections, was determined to be cod liver oil.

"The condition apparently is not so rare as

has been assumed, and there is considerable evidence that oils and fatty substances given to infants by mouth or introduced into the nose, either for purposes of medication or for food, find their way into the lungs. The removal of oily material from the alveoli and the absorption of the oil is a comparatively slow process, and the end result is similar to the reaction to any other inert foreign body.

"An acute infectious pneumonic process is usually super-imposed and according to Pinkerton is probably the immediate cause of death. As regards the clinical diagnosis, it may be possible to diagnose the condition by finding oil-laden phagocytes in the sputum. However, the difficulty of obtaining the sputum from infants is sometimes extreme. Clinical and X-ray evidence yield no definite characteristics of diagnostic value.

"The means of avoiding such dangers as this condition presents are obvious, such as keeping to a minimum the amount of oil used for nose drops, incorporating oily substances used for medication directly into the food, and the use of the greatest possible care in tube feeding."

## THE FULL-TIME SECRETARY

Many State Medical Societies are considering the employment of a full-time secretary, who would also edit the Journal of the Society. The Colorado State Medical Society has the appointment of such an officer under serious consideration. The June issue of *Colorado Medicine* has the following editorial comment on the plan by the Secretary, Dr F B Stephenson:

"Can we finance a full-time secretary?"

"The answer is yes, if we are willing to contribute individually a yearly trifle.

"Having conferred with other State Societies, I have learned that a suitable man likely cannot be obtained for less than \$5,000 per year, some societies paying \$6,000 or more besides maintaining offices and paying traveling and other expense.

"Our present financial status would at first sight seem to prohibit the undertaking. The income to our General Fund is now about \$2,200 (\$2.00 per member), and to *Colorado Medicine* a like amount, making a total of \$4,400 in addition to which \$1,100 (\$1.00 per member) goes to the Special Fund for Education of the Public in Medical Affairs. It is

plain that with the present distribution of dues, and with the present membership, more money would be needed for the plan. The two means of raising money besides raising the dues are—first, increasing the advertising and subscription of our Journal, and second, bringing in new members. The secretary and the editor are agreed that a secretary-business manager, employing his whole time, could make *Colorado Medicine* pay its own way, and records of doctors located in Colorado show a roundly large number of eligibles who do not now belong to the State Medical Society.

"Pay the officer a salary of \$4,000 plus traveling and incidental expenses for the first year and let him devote his time largely to stimulating constituent society activities, increasing membership, and putting *Colorado Medicine* on a self-supporting basis. Consider a raise in dues of \$1.00 as a tentative measure, making \$5,500 available the first year, then allow the new executive to work out his own salvation in this manner.

"The plan given contemplates dues of \$6.00

(Continued on page 1050, adv xii)

(Continued from page 1051, adv xiii)

an area of dullness and tubular breathing. The sounds may be absent if the infarction is distant from the surface. Symptoms pass off in from a week to ten days. Embolism differs from an ordinary pneumonia in its mode of onset its lesser severity and shorter duration.

"A patient aged 49 at our hospital started to get out of bed 14 days after a perforated gastric ulcer had been excised and a gastroenterostomy performed, to put on his clothes preparatory to going home. He fell back in bed and died without speaking. Such cases may be due to a fragment of clot reaching the medulla, although with a massive clot the strain on the heart may be sufficient to cause an immediate dilatation of the heart.

"The primary condition is the formation of an intravascular clot. The situation of this primary clot is in the internal and external iliac veins or at the point where they join to form the inferior vena cava as shown by the few cases in which complete reports are available. Many writers have assumed that the clot originated at or near the site of operative interference but little or no proof has been discovered post mortem. When we consider that more than half of the cases are comprised of gall-bladder, stomach and appendix cases, all of which have their veins draining into the portal system, yet the embolus which caused death passed into the right auricle and plugged the pulmonary artery, the thrombus, therefore, was not formed in the operative area but almost certainly in the iliac veins or inferior vena cava.

"Operations above the diaphragm rarely result in pulmonary embolus because venous stasis cannot occur in the superior vena cavae. Operations upon the pelvic organs more frequently result in embolism than operations in other parts, due to the large veins which may be injured by the position used in such operations, by the presence of retractors and packs in the pelvis in the proximity of veins, and by the immobility of the patient after operation. It is further noted in favor of venous stasis as the chief cause of thrombosis that it occurs much more frequently in patients whose circulation is poor from toxemia, anemia or any cause.

"There is a very prevalent belief that embolism is due to sepsis, but this seems an untenable theory.

"Before thrombosis can occur two factors must be present.

"1 A certain amount of thrombokinase derived from the tissues and liberated by the wound must be present in the blood.

"2 There must be venous stasis.

"The sequence of events then would be, as a result of a wound thrombokinase is liberated from the tissues, and gains entrance to the blood.

per member, of which \$1 00 would continue to go to the Special Fund. If the Society wished to do away with further accumulations in the Special Fund, leaving the present nest-egg of \$6,811 82 for several years, the above plan could be followed with no change in amount of dues until such time in the future as the need arose for replenishing the Special Fund.

“In view of the fact that the State Society does not now and never has paid rental or service charge to Denver on the score of the library, it might be arranged to house the new executive in the library and pay the Denver Society, say \$600 00 per year for rental and library service. This would be a part of the expense included in the estimate above. It would allow the Denver Society to pay its \$6 00 per member to the State Society and still maintain the library on the present basis.

“Is our Society worth as much to us as Rotary, or Elks, or Chamber of Commerce are to their members? Aren’t our dues really paltry considering the importance of our organization?”

## PULMONARY EMBOLISM OF POST OPERATIVE ORIGIN

The July issue of the *Nebraska State Medical Journal* contains an article on Post Operative Pulmonary Embolism. From the following abstract is taken:

The incidence of fatal cases in five large hospitals has varied from one in 600 cases under going operation to one in 2,000 cases. About ten times that number of non-fatal cases occur. The condition is therefore fairly common, and is an ever present risk in operative surgery.

The curve of frequency is very low for cases under 40 years of age, and reaches its maximum from 60 to 70 years. It is most frequent on the 8th day after operation, but may occur from the first minutes up to the 8th week.

Dyspnoea is the most constant symptom, its degree varying with the extent of the lung area from which blood is excluded.

Pain in the lower chest is another constant symptom.

“When pulmonary embolism occurs the dangerous period is the first few minutes, and if the patients can survive the first ten minutes they survive oftener than not, provided that secondary pneumonia does not intervene and even if it does, more get well than die.

“In the non-fatal cases the dyspnoea soon wears off, the pain in the chest subsides, the temperature rises and a cough soon develops. During the next few days the sputum may be streaked with blood. Chest examination reveals

(Continued on page 1051, adv xiii)

(Continued from page 1052, adv xiv)

cholera is told in the following quotation "The bathing place of the pilgrims is 650 feet long by about 80 feet wide, shut off from the rest of the Ganges by rails. Into this long narrow enclosure, the pilgrims from all parts of the encampment crowded as closely as possible from early morn until sunset. The water within this space was during the whole of the time thick and dirty, partly from the ashes of the dead brought by surviving relatives to be deposited in the waters of the river god, and partly from the washing of clothes and bodies of the bathers. Now pilgrims at the bathing ghat, after entering the water, dip themselves under water three or more times, and then drink the holy water whilst saying their prayers, the drinking of the water is never omitted. The quantity of water drunk by the bathers varies, but it is never less than about as much as can be taken up by the palms or two hands held together, so as to form a cup and usually several cupfuls are drunk.

"When we remember that a large proportion of the million or two pilgrims come from the great Bengal United Provinces endemic area I have described, and travel long distances through it, it would be a miracle indeed if cholera did not appear among them, in spite of the elaborate sanitary arrangements made by the Government for the occasion, as occurred in 1867, regarding which Cutcliffe recorded that the health remained good until the 11th April, but on the evening of the 12th there were several undoubted cases of cholera, and on beginning to disperse on the morning of the 13th, 'every section of the great multitude had become contaminated with cholera, and every one of the streams of returning pilgrims had cases of the disease within one day's journey of Hardwar, and it clung to them till their arrival in their homes in the most distant parts of the province.'"

Concerning the spread of cases in the Punjab, the author says

"The first cases among residents occurred in persons who had been in close contact with pilgrims. In no single instance did the disease appear in a station before the arrival of the pilgrims. The facts leave no doubt of the transmissibility of the disease and of the pilgrims being the vehicle of its importation into the Punjab."

The author has traced the origin of some of the epidemics, and has given the histories of the first known cases at some of the shrines, and has traced the incidence of cases which have occurred almost daily thereafter at the shrine and along the return routes of travel of the pilgrims.

stream by the lymph route or directly. Thus enables a clot to form in those veins which for the time being good is stagnant or nearly so.

'Granting that venous stasis does favor thrombosis then the second phase is easy of comprehension. A small bit becomes loosened, passes through the right side of the heart and on into the pulmonary artery obstructing the right or left or even both.

"If the embolus is small we simply have infarction of a small area (post operative pneumonia) which usually clears up nicely. If the embolus be large, death may ensue with great rapidity."

"The treatment is preventive, and consists in the avoidance of injury to the veins during the operation, and of anything which would cause venous stasis.

"The article concludes

"Although this subject is a difficult one, the causative factors far from definitely proven, the means for preventing embolism so uncertain and the treatment so unsatisfactory, it is a great thing that surgeons have at last begun to enquire how they may avoid this dreadful complication, and it is to be hoped that in the near future we shall be able to solve this problem completely."

## CHOLERA IN INDIA

The May issue of the *Indian Medical Record*, which is published in Calcutta, contains an article on the epidemiology of cholera and an editorial advocating the use of Hoffkine's vaccine as a preventive.

The epidemiological article is by Sir Leonard Rogers, M.D., who has studied the incidence of cholera in the several sections of India, beginning with that in 1817 in the Ganges Valley. This epidemic began in Bengal in the latter part of 1817, declined as usual in the cold weather months in Western Bengal (now Bihar and Orissa), increased again as usual in March, 1818, and spread with rapidity, never since equalled, north west over the United Provinces to the Punjab and south through Central India, Hyderabad State and the Bombay Deccan, overran to Madras by the end of the year, and passed to Ceylon in January, 1819, the Indian Peninsula having been free from cholera from some years previously.

The author shows the relation of humidity and rainfall to cholera, but he lays the greatest stress on the great religious pilgrimages to holy shrines on the Ganges and other rivers. While numbers of pilgrims visit these shrines every year, great pilgrimages occur every twelve years, and these are the great cholera years. How the pilgrimages spread

## VISITING HOUSEKEEPERS

A considerable proportion of the time of a public health nurse is devoted to educational work along the lines of simple house-keeping. The City of New Haven finds so much of this work to be done that it employs five house-keepers to go into the homes of the sick and needy, and help and instruct the caretakers in the elements of housekeeping. The work of these visitors is told in the following article from the May issue of the *Monthly Bulletin* of the New Haven Department of Health—EDITOR'S NOTE

"At the present time there are five Visiting Housekeepers on the Staff of the Visiting Nurse Association. They are trained and supervised by the Dietitians of the Home Economics Department. These workers spend from two to four hours in a home where the visiting nurse finds help is needed in solving some of the home making problems. The family pays 35 cents an hour if they can afford to do so.

"Here are five types of cases being carried at the present time. Mother ill, a new baby and no one to help in caring for the home or other children. The Visiting Housekeeper spends two or three hours every day preparing food for mother and family, and making the home neat and tidy, until mother can again resume her duties.

"A child needs medical attention and there are three other little tots in the family. The Visiting Housekeeper stays in the home and continues mother's duties while she takes the child to the physician for treatment, or if the mother is unable to go, the Visiting Housekeeper takes the child.

"A young girl has been left in charge of several younger sisters and brothers. The mother is dead, and this girl needs a helping hand in keeping house. Many a mother needs instruction in the preparation of good nourishing food, or needs to be taught how to keep house, by having a Visiting Housekeeper work with her.

"It may be a young mother needs help in making a layette. Often-times clothing is given away without a thought as to how it may fit the wearer. The Visiting Housekeeper teaches the mother how to use a pattern, sew and remodel old clothing.

"Many chronic cases carried by the Visiting Nurse Association need a Visiting Housekeeper two or three times a week to do a few necessary things they are unable to do for themselves. The work of the Visiting Housekeepers supplements that of the nurse, enabling her to do a better piece of public health work."

### PHYSICIANS IN RURAL COMMUNITIES

The Nebraska State Journal for June comments on the availability of physicians in rural communities as follows:

"The lay press has featured under bold headlines two facts brought out in a report of a survey made by Miss Anna Cameron (Nebr. Univ. Extension Dept.) of conditions in about sixty counties in Nebraska. That there are six counties without railroads and two counties without a doctor. On the face of this statement it looks bad. Pennsylvania, with an area about two-thirds that of Nebraska and with a population about 6 times as large, has one county without a railroad, but it has highways and motor cars—so do Nebraska counties without railroads. A town, without a physician, twenty-five miles from a railroad in these days of highways and automobiles, is no worse off than were the farmers ten miles from any Nebraska town before the days of the auto. It seems certain that it is not a scarcity of physicians, but lack of support, that keeps physicians away from these small isolated places."

(Continued from page 1053, adv xv)

The editorial in the *Indian Medical Record* for May, says

"Bengal is now in the throes of its annual epidemic of cholera which exacts an annual toll of at least 30,000 lives. The most lamentable thing about this appalling sacrifice of human life is that it is wholly avoidable. In many European countries that used formerly to suffer severely from cholera the disease is now entirely unknown. Recently we have had striking proof that eastern countries can also be freed from cholera by preventive measures and anticholera inoculation. Thus in both Java and Korea cholera has been entirely stamped out by the widespread use of cholera vaccine and in the Philippines and French Indo China also the disease has been greatly reduced by the same means.

"During an epidemic of cholera in Japan the anticholera vaccine was used with great success. The Dutch authorities of Batavia following the example of Java decided in 1914 on mass inoculation with anticholera vaccine. More than 60 per cent of the population of Batavia were inoculated and the results were remarkable. In September of that year there were 110 cases, in October it rose to 606, fell in December to 26, in January only 3 and since

then Batavia is almost free from cholera. In 1919 the Government of Java issued 5½ million c c of the vaccine and the population of Java was 35 millions. It can thus be easily seen that a large proportion of the people was inoculated. The result was that during the last four years there had not been a single case of cholera in the whole island.

"The example of Java was followed by Bagdad. In a short space of time practically the whole population were inoculated with the result that cholera disappeared almost immediately and had never appeared since, according to the last reports.

"Strangely enough the method of prevention of cholera that has been used with such success in many countries was never tried in Bengal, the home of cholera, where the vaccine was first prepared by Hoffkine. It was left to a popular minister to take up this vital problem in right earnest and Bengal will remain ever grateful to the Hon'ble Mr. Gannanji if cholera is stamped out from Bengal through his efforts. A laboratory has already been opened for the preparation of the vaccine on a large scale so that in the near future it can be supplied free in sufficient quantities to enable mass inoculation of the whole population of Bengal possibly."

## THE ACTUAL ACHIEVEMENT OF MEDIAN PERINEAL PROSTATECTOMY, AN ANALYSIS OF TWENTY-FIVE CONSECUTIVE CASES, ILLUSTRATING THE AUTHOR'S METHOD\*

By PARKER SIMS, M D, NEW YORK, N Y

**I**N selecting a method of surgical treatment for cases of prostatic obstruction, it is but right and proper that one should select the safest and the best

I believe that median perineal prostatectomy is the best operative procedure that has been thus far developed. If this is a fact, it must be susceptible of demonstration.

The best way to estimate the merits or demerits of any procedure is to study a consecutive series of cases. Of course, it would not do to select a group of favorable cases on the one hand nor would it be fair to take an unfavorable group on the other hand,—but a consecutive group.

For this purpose, I am recording and analyzing twenty-five consecutive cases which I deem to be a sufficient number. This group embraces a wide enough variety to afford a good demonstration of not only what was accomplished but of what we may expect to accomplish.

These twenty-five patients were operated upon by my method of median perineal prostatectomy and were treated according to my present day methods.\*\*

It will be noted that these cases occurred during the time that I have been using sacral anesthesia. They also embody practically all of my present day methods and modifications, so that I feel that they not only demonstrate what occurred but what we may reasonably expect to accomplish in succeeding series of cases.

The average age of these twenty-five patients was 64 years and 4 months. Nineteen were between 60 and 75, five were between 50 and 60 and one was under 50 years of age.

All of these patients had residual urine, some in only a small amount. Six of them had complete retention some with overflow.

While the blood chemistry of the majority of these cases showed a high retention of urea nitrogen, of N P N and of creatinine, only two numbers 7 and 20 showed such high retention that I felt called upon to resort to preliminary decompression of the kidneys. All the others were fit subjects for a one stage operation.

Patients who had had a large amount of residual urine, for any length of time, showed the highest blood retention.

In 18 of these cases, I employed the X-ray to determine stone in the bladder. The X-ray revealed stone in numbers 12, 14 and 15.

A bladder stone was overlooked in case number 9 because I depended upon the fact that a well known urologist had used the cystoscope and had pronounced the patient free from stone. This was unfortunate, for owing to this assurance, I did not search for a stone and remove it. The consequence was a continued pyuria and a later operation.

I personally employed the cystoscope in examining five of these patients numbers 7, 15, 16, 17 and 20. These were the only cases in which I deemed a cystoscopic examination of importance. In each of these the cystoscopy was performed at the time of operation which is much safer than employing it at the preliminary examination.

The cystoscope in these cases is often dangerous and sometimes misleading. I am glad to know that many prominent genito-urinary surgeons feel as I do about this matter.

In cases 9 and 13 other urologists had used the cystoscope as a means of preliminary examination. In case number 9 this was misleading. In case number 13 the result was serious. The patient suffered severely from the traumatism. He had a profuse hemorrhage filling his bladder with blood and requiring several days of difficult preliminary treatment before the operation could be undertaken.

These cases and many others have fortified me in the belief that the cystoscope should not be

## REPORTS INTERESTING CASE

One of New York's leading surgeons reports the following case. A structure steel worker fell four stories. Examination proved that he had sustained an intratrochanteric fracture with the upper third of the femur badly comminuted. An enlarged hematoma with excessive drainage and skin abrasions made it impractical for any form of closed dressing treatment to be employed for the first ten days. At the end of this time, however, a combination PNEUMATIC REDUCTION and AMBULATORY splint was applied. Before the application was completed the patient had gone to sleep. He slept for twenty-four hours, and really rested in comfort. An X-ray examination showed the bones in anatomical apposition. The patient was then kept in bed for two weeks longer due to fractured ribs and hand injuries. During this time he was daily rolled in bed, back massaged, and slept on his side as well as his back. Now, at the end of four weeks with the splint on, he has had two weeks of what might be called solid walking treatment, during which time he has been all over the hospital, even on to the roof. His appetite has noticeably increased, and his bowels function better. He has to a great extent regained his strength, and in reality is going through his treatment and convalescent period in one. The X-ray examination shows the bones still in anatomical apposition, and an unusual amount of callous formation for so short a time due undoubtedly to the fact that it has been stimulated by the slight irritation which has taken place at the seat of the fracture.

**WANTED**—Salaried appointments for Class A physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nationwide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Chicago. Est. 1895. Member the Chicago Association of Commerce.

**FOR SALE**—Eye, Ear, Nose and Throat practice, and residence in city of 40,000 up state. Established for 30 years. Reason for selling, wish to retire. Easy terms to right man. Details on application. Address, Box 85 New York State Journal of Medicine.

### FOR SALE

Owing to Physician having died, modern home and offices with established practice in village of 6,500 population and large adjacent rural community. Offices are complete in all detail and include full equipment. Attractive terms. For details write Mrs. I. M. Schneible, Greenwich, N. Y.

**FOR SALE**—Office equipment of the late Dr. A. B. Berk, consisting of Wappler X-Ray Machine, numerous valuable instruments and library, especially of interest to dermatologists, at very reasonable figures. Rare opportunity. 667 Madison Ave. Phone Regent 2512, -10-4.

**YOUR OPPORTUNITY DOCTOR!** Village of six thousand central New York. Five factories. Trolley to adjacent city. Two doctors. Best location in town. For particulars write A. F. Wright, Dundee, N. Y.

have found them a blessing. It has been a pleasure to be of service. Our reputation of more than thirty-five years is behind every elevator we install and to us the profit in any sale is of less importance than the opportunity the transaction affords to make of the purchaser a permanent friend.

For full particulars see advertising page No. XXIV of this issue of your JOURNAL.—Adv

Horlick's Milk Modifier, a new product made by the Horlick's Malted Milk Corporation, Racine, Wisconsin, is now being introduced to the medical profession. This maltose and dextrin product, which is derived exclusively from malted grains, was first announced at the annual meeting of the American Medical Association in Washington, D. C., in June, and created much interest. Since that time it has been presented to convention gatherings in other parts of the country, and the Horlick representatives are now calling on individual members of the profession.

Horlick's Milk Modifier is presented and supplied to the profession along ethical lines. No feeding directions accompany the package. A statement on the wrapper is to the effect that the product is for prescription by physicians only.

In conformity with the Horlick policy, the Milk Modifier is put up in hermetically sealed glass jars only. The one-pound size retails at \$1.75 and the five-pound jar at \$3.00. The fact that it carries the name "Horlick's" is a guarantee that only the finest materials are used.

In the June 18th issue of the *Journal of the American Medical Association*, under the heading of New and Non-official Remedies, the acceptance of the Horlick Milk Modifier was announced by the American Medical Association. The product differs from the malt sugars in that it incorporates soluble and readily assimilable protein and valuable mineral salts from the grains. The Horlick firm points out this fact as a decided advantage for its product.

Another point which is mentioned as an advantage in favor of the new product is the proportion of its two chief carbohydrates, maltose and dextrin, which are 63 per cent maltose and 19.5 per cent dextrin.

Samples of the new product, literature concerning its use, prescription blanks and file cards giving methods of preparation are available for members of the medical profession and will be sent upon request. Adv

Syracuse, N. Y., Sept. 15, 1927

Dear Doctor:

Our method of mail order selling saves you not only salesman's expenses but the valuable time given to salesmen.

One of our catalogues and a few minutes time once a week or two will give you hours for other work or rest.

MUTUAL PHARMACAL CO., Inc

1—Posterior surface of sacrum showing needle in hiatus sacralis

2—Showing simple median incision in perineum  
There is no dissection and but a single sweep of the knife

3—Knife entering the lithotomy staff and dividing the membranous urethra.

4—Showing Sims' rubber tractor within the bladder, pulling prostrate toward the surface (I am now using Young's tractor instead of my own)

5—Showing Sims' tractor in situ. Incision in sheath of prostrate is shown ready for enucleation

6—Showing Young's tractor in situ. Incision in sheath of prostrate is shown, ready for enucleation

#### PARKER SYMS' TECHNIC OF MEDIAN PERINEAL PROSTATECTOMY

used as a routine in the preliminary examination of the patient. The cystoscope will not tell us whether or not to operate, it may be of aid in telling us how to operate, but only in exceptional cases

Many years ago, I operated upon a man whose case had been "worked up" by a urologist of international repute. He had prepared for me a picture of the bladder interior as revealed to

him by the cystoscope. He pronounced the patient free from stone and yet when I operated I removed fifteen stones from his bladder.

Sacral anesthesia was attempted in twenty-four of these cases. It proved successful in all except four. In three of these, we found a defective solution had been used. In case number 22 bleeding in the sacral canal occurred when the needle was introduced. As this could not be

cleared up by re-adjusting the needle, the injection was not made

Case number 4 had had a supra-pubic prostatectomy performed three and a half months previously. As his supra-pubic wound had never healed and had to be operated upon we did not employ sacral anesthesia

In this series there was one other patient who had had a supra-pubic prostatectomy performed without relief of his condition. Both of these patients were cured by perineal prostatectomy

### RESULTS

There were no deaths

The result in case number 14 was the only one which was not as satisfactory as could be expected. The enucleation of his gland was incomplete, and he was to have had a re-operation, but before this could be undertaken he was killed in an automobile accident

Patient number 7 had a carcinoma of the prostate. The immediate result was most satisfactory. He made a good operative recovery and was able to leave the hospital on the 19th day. His obstruction was relieved. He is still living and only complains of the fact that a little urine comes thru the perineum, his wound having reopened on account of his cancerous condition

Patient number 9 made a remarkably fine recovery from his operation. He had bladder control from the time of operation. He left the hospital on the 9th day, and everything would have been super-fine had it not been for his undiscovered bladder stone

Post-operative epididymitis developed in four of these cases. In cases 10 and 11 it was so slight as to be insignificant. In case 23 it was annoying because it necessitated the patient taking to his bed again for a few days. In case 21 it amounted to a severe complication, resulting in destructive orchitis, necessitating an orchidectomy

Patient number 21 had an accident which delayed the healing of his wound. The outer fibers of his anal sphincter were torn in an attempt made by one of my assistants, to catheterize him thru the perineum, (wound), a few days after his operation. This is a thing that should not occur. It had nothing to do with the operation. When the patient left the operating table his bladder sphincter was intact and held water, and his rectal sphincter was absolutely undisturbed. Dr. James Vander Veer kindly assisted at this operation

I lay stress on the fact that by my method of operating there should be no danger of wounding the rectum, and I believe this technique shows

great superiority over the dissecting methods. In the latter, perforation of the rectum has often occurred. When it does, it is so disastrous that I believe that that fact alone has been a great setback to perineal prostatectomy

Of these twenty-five cases all had bladder control from the time of operation with the exception of case number 7. He had perfect control from the fifth day

By bladder control, I mean that the sphincter muscles are intact and that the patient is able to hold his urine. Some of them did not exercise this ability at all times, from the start, but as soon as they learned just what it meant, they were able to keep dry and to be up and about

Urine begins to come thru the penis when the wound gets sufficiently small. In other words, when the wound ceases to be the line of least resistance. In these cases this happened never later than the 9th or 10th day. In six cases as early as the 3rd day. In other cases on the 4th, 5th, 6th and 7th days

The final wound healing was satisfactory in all these cases except number 7. His wound reopened on account of his cancerous condition. The healing in case number 21, who suffered a lacerated anal sphincter after the operation, naturally was retarded but finally healed

For one reason or another the complete healing of the wounds was slow in cases numbers 3 and 24. A minute sinus persisted for a time but finally closed completely. This did not interfere with their bladder functions nor prolong their period of disability

Usually the healing of the wound is a detail which gives us but little concern as the patient is able to be up, out of the hospital and going about his affairs, requiring treatment only two or three times a week. It does not matter particularly whether or not his wound is actually healed so long as it is healing

All except two of these patients were able to be up and about on the 1st or 2nd day after the operation and every day thereafter. Patient number 25 was confined to his bed for two days. Patient number 3 was able to be up on the 4th day but had to resume his bed on account of uremia and a weak heart, and his convalescence was a long one

Twenty of these patients were able to leave the hospital within two weeks after the operation. Eleven of them were able to leave within the first week

By able to leave the hospital, I mean that they could hold their urine so as to keep their clothes dry and were sufficiently recovered so that they could go about under their own power

# THE TREATMENT OF CHRONIC SUPPURATIVE OTITIS MEDIA WITH TUBAL PERFORATION WITH THE AID OF THE CATHETERIZING EUSTACHIOSCOPE CASE REPORTS\*

By LOUIS K PITMAN, M D, NEW YORK, N Y

**C**HRONIC suppurative otitis media is characterized by a chronic inflammatory process arising from various pathological lesions which involve one or more areas of the mucosa and bony structures which comprise the middle ear, the most common symptom of which is otorrhea, (Phillips) I bring this definition before you with one aim in mind, and that is to remind you that the infection is limited to one or more areas of the middle ear. The middle ear consists of the Eustachian tube, the tympanic cavity and its contents, the attic, antrum and mastoid cells. Therefore, to obtain best results, it is necessary for us to know the location of the pathological process, so that we may limit our treatment to the portion of the middle ear infected.

The Law of Koerner—"That a complication of an ear disease is in the immediate neighborhood of the primary focus"—can be very well applied here to help us localize the area affected. That is to say, "the location of the perforation in chronic suppurative otitis media is in that portion of the drum which is in the immediate neighborhood of the infection."

Fig 1—Location of Perforation—(a) Anterior superior quadrant, or the whole anterior of the drum the suppuration is in the Eustachian tube, (b) The kidney form or heart perforation speaks for an infection both in the Eustachian tube and antrum, (c) A marginal perforation immediately above the short process of the malleus (Shrapnell's membrane) signifies an attic suppuration, (d) A perforation of the tympanic membrane at the posterior superior quadrant or posterior part together with destruction of the antrum wall speaks for an antrum suppuration, (e) A perforation of the inferior margin of the drum membrane signifies necrosis of the inferior wall or floor of tympanic cavity

It may be said in general that if the perforation is marginal, there is bone necrosis in the region of the perforation, thus making treatment more difficult. If the perforation does not involve the margin of the drum, bone necrosis is

absent, the case being one of simple chronic suppurative otitis media.

It is my aim in presenting this paper to limit the discussion to the treatment of that part of chronic suppurative otitis media, where the infection is limited to the Eustachian tube, characterized by anterior perforation of the drum membrane (Fig 1a).

The rational treatment of such cases would be to cure the continued infection from the epi-pharynx, viz, infected sinuses, tonsils, adenoids, etc. Nevertheless, in the majority of such cases where we remove the causative infection in the naso-pharynx, the otorrhea is still present and the chronic suppurative otitis media has not improved. This is due to the fact that the mucous membrane of the Eustachian tube, when normal, is covered by ciliated columnar epithelium, which propels the secretions toward the pharyngeal orifice of the tube. In chronic infected processes, the cilia are lost or their wave-like motion is inhibited. The isthmus of the tube forms a barrier to the downward flow of the secretion from the tympanic end of the tube. Therefore, additional local tubal treatment is necessary.

To carry out this local treatment, Weber-Liel used a small long flexible hard rubber catheter, placed inside of a large catheter (catheter guide) of usual length. The larger catheter (catheter guide) is passed to the pharyngeal orifice of the tube, and the smaller one is introduced through it to the isthmus of the Eustachian tube. A small syringe filled with a mild antiseptic is then attached to the smaller catheter and forced through the Eustachian tube into the tympanic cavity, and out through the perforated drum. This procedure is repeated at intervals until favorable results are obtained.

This treatment which is both logical and practical is neglected for the want of a safe and better instrument.

The Weber-Liel instrument has the following drawbacks:

(1) The introduction of the catheter into the Eustachian tube is not done under direct vision.

(2) The rubber catheter although flexible is too hard for safe use, and abrasions to the mucous membrane lining the Eustachian tube is very common, particularly when constant repetition of treatment is required. No matter how much care is taken, one is apt to produce a false passage, and the medication is forced into the sub-mucous tissue, and this evokes an alarming swelling.

(3) The fact that the catheter guide has been passed to the pharyngeal orifice of the Eusta-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 10 1927

chian tube and air has been forced through it into the tympanic cavity is no criterion that the rubber catheter can safely be directed through it into the Eustachian tube without creating a false passage. The accompanying diagram illustrates this point.

Fig 2—This illustration is self-explanatory why air may enter the Eustachian tube and not a catheter.

To overcome these difficulties I devised an instrument, "The Catheterizing Eustachioscope," which makes Eustachian tube catheterization and treatment a safe and simple matter. By direct vision a No 4 to No 6 kidney catheter adapted for this purpose can be introduced as far as the isthmus of the Eustachian tube or tympanic cavity in a few seconds.

It consists of a pair of catheter guides—right and left—and a naso-pharyngoscope. The illustration (Fig 3) shows the right guide attached

Fig 3—Catheter Guides—right and left, and Naso-Pharyngoscope.

to the naso-pharyngoscope, and also the left guide separate. The guide can be slid along, also rotated about the naso-pharyngoscope. In operation, the catheter guide, containing a catheter, is attached to the naso-pharyngoscope, so that the egress portion extends along side the mirror. In this position, under slight cocaineization, the combined instrument is easily introduced into the naso-pharynx, under the inferior turbinate, in the same manner as an ordinary Eustachian catheter. Then nasal orifice of the Eustachian tube is then brought into view, the guide, containing the catheter, is given a slight turn to increase the visibility of the catheter, and its free end is introduced into the Eustachian tube.

Two guides are provided, one for the right ear and one for the left, because the same guide cannot be rotated to either side of the instrument without changing the direction of entry.

The advantages of this instrument over the Weber-Liel are as follows:

(1) The catheter is introduced into the Eustachian tube under direct vision.

(2) I use No 4 to No 6 kidney catheter exclusively for this work, which is much more flexible than the hard rubber catheter and yet not too soft for this purpose. When the catheter meets any resistance within the Eustachian tube it will bend on itself at the region of the nasal orifice, visible through the naso-pharyngoscope, and warn the operator not to use too much force.

(3) The catheter guide has a shorter curve at its end, and by not entering the nasal orifice of the Eustachian tube, both allows the kidney catheter room enough to adjust itself, and also does not unduly hamper its direction of entry.

The treatment of chronic suppurative otitis media with tubal perforation, consists of irrigating the Eustachian tube (as illustrated in Figs 4, 5 and 6) with 3 to 5cc of 20% argyrol.

Fig 4—Introducing Catheterizing Eustachioscope into the Naso-pharynx under the lower turbinate after cocaineization as in ordinary catheterization.

at each sitting for about 15 sittings. The washing is done twice weekly. When the discharge is fetid, the following has been helpful in conjunction with the washings:

R/x	Formalin	m5
	Hydrargyr	gr 132
	Alcoholis	oz ss
	Aqua dest	qs ad oz iii
gtts 5 in ear 3 times daily		

This series consists of nine consecutive cases.

The functional test showed in all cases a middle ear impairment, before and after treatment. There was a noticeable improvement of hearing with the progress of treatment, as tested by a spoken and whispering voice, and the majority called my attention to the fact that their hearing became more steady.

Five of the series showed anterior perforation of the drum membrane but not marginal. One case was of a bilateral condition, thus presenting an opportunity to employ two methods of treatment for comparison, (see chart, patient 5).

Case No	Sex and Age	Ear	Condition of nose and pharynx	Previous treatment	Duration of Running Ear	Location of perforations	Type of discharge	Number of irrigations	When treated	Remarks
1 J K.	male 28 years	Right	atroph rhin	local nose treat	7 years constantly	anterior but not marginal	mucopur none fetid	14	Apr 28, '26 to June 12, '26	Patient's ear still dry Last visit May 2, '27

CASES OF OTITIS MEDIA TREATED BY MEANS OF THE CATHETERIZING EUSTACHIOSCOPE

Fig 5—Eustachian orifice brought into view by the observing telescope Catheter introduced into Eustachian tube.

Fig 6—Patient bends head toward the affected side. Medication is forced through the Eustachian tube by way of the catheter, running out through the perforated drum and the external canal

The other four of the series showed anterior perforation, marginal type. One case was of a bilateral type thus also presenting an opportunity to employ two methods of treatment, for comparison (see chart, patient 8)

The foregoing cases are presented because of the several different conditions represented and because the results obtained in the application of

both the old and new methods in bilateral cases. Although owing to the newness of the instrument the number of cases so treated is extremely inadequate for positive conclusions, the results obtained are so gratifying as to warrant the introduction of this method among otologists with a view to determining its actual possibilities after more extensive use.

## TREATMENT OF LUPUS ERYTHEMATOSUS WITH GOLD COMPOUNDS (Sodium Salt of Aurothiobenzimidazol Carboxylic Acid)

BINFORD THRONE, M D, A. SCHUYLER CLARK, M D, LAIRD S VAN DYCK, M D  
and  
C N MYERS, Ph D

From the New York Skin and Cancer Hospital, New York City

EUROPEAN investigators have recently directed their efforts toward the study of tuberculosis through the application of gold preparations. These efforts have led several European dermatologists to try this form of therapy in the treatment of Lupus erythematosus on account of its supposed relationship to tuberculosis. Martenstein (1922 and 1926), Ullman (1923 and 1924), Volk (1925), Bruhns (1924), Jeanselme and Burnier (1926), Galewsky (1924 and 1926), Stein (1922) and Havenstein (1924) were pioneer investigators along this line.

In 1922 Martenstein used a preparation called "Krysolgan," which was prepared by Feldt in 1917 and chemically is the sodium salt of 4 amino-2-aurothiophenol carbonic acid. The results with this preparation seem to have been variable, some observers reporting cures. Ullmann reported successful results in eight cases. Volk treated twenty-seven cases with favorable results. Nobel, on the other hand was unable to substantiate Ullmann's claims.

In 1924, Mollgaard of Copenhagen, reported on a gold compound of thiosulphuric acid called "Sanocrysin." This preparation has been extensively employed in tuberculosis, but recently it was employed by Schamberg et al (1926) in the treatment of Lupus erythematosus.

Galewsky (1926) has presented a report on the treatment of Lupus erythematosus, stating that Krysolgan was a tremendous improvement as compared with the first gold preparation, "Aurocutan" (monocantharidyl-ethylene-diamin-auros cyanide). However, it caused a series of unpleasant after-effects, severe exanthemata, and three deaths that were reported by Stein, Havenstein and Bruhns. No recent deaths have been reported. Galewsky thinks that with improvement of the drugs and the technic, it is possible to avoid these severe symptoms.

He further states that Sanocrysin produces even more severe after-effects than Krysolgan, and according to a report from Vienna, its use in the treatment of Lupus erythematosus

had to be discontinued on account of the danger

More recently, Schamberg, Harkins and Brown (1926) in the United States, presented a fairly complete summary of the application of gold compounds in tuberculosis, and have given a preliminary report of their results obtained with these preparations in the treatment of experimental tuberculosis of the skin in animals. They summarize their results as follows

"While we cannot claim to have prevented the generalization of tuberculosis in inoculated guinea pigs and rabbits by means of injections of gold compounds, we have observed a demonstrable influence on the cutaneous lesions, and in some animals a considerable prolongation of life beyond the average of the infected controls"

"No absolute deductions can be drawn from the experiments here reported. We believe however, that they indicate that a favorable, though not curative, influence is induced by gold therapy. Taken in connection with the work done abroad, they offer the hope that perhaps with a more ideal gold compound something may be achieved in the treatment of cutaneous or of general tuberculosis"

In spite of these recent reports, it must not be overlooked that gold and sodium thiosulphate was prepared as early as 1845 by Fordos and Gellis. Mollgaard's modification of this preparation of gold is said to utilize from 90 to 95 per cent more gold than that which was combined in the original product. The gold and sodium thiosulphate prepared by the older methods contained only from 10 to 15 per cent of gold. This, however, is due to method of preparation and by means of these improvements, a preparation of higher gold content is obtained.

Mollgaard's Sanocrysin contains about 37.5 per cent gold and 26.2 per cent sulphur. Some preparations of gold and sodium thiosulphate have an extremely low gold content. In this respect the clinician should be on his guard in applying preparations of varying gold content. Some preparations have an extremely high gold content and some very low, so unless the gold content is noted, comparative clinical results cannot be attained. Similar consideration must be given to the toxicity, stability and solubility of the preparation, in addition to toleration by the patient.

The next gold preparation to appear was "Triphal," which is the sodium salt of aurothiobenzimidazol carboxylic acid and has the chemical formula  $C_{10}H_7N-NH-CSAu-COONa \cdot 2H_2O$ . Shortly after this, another compound called "Auophos" was developed. This preparation is chemically the sodium gold double salt of aminoarylphosphinic acid and hyposul-

phuric acid. The toxicity of Triphal, according to Galewsky, is 0.1 gram per kilogram of rabbit. Its dosage is 0.025 to 0.200 gram. It can be given three times a week.

The clinical experience of a few of the important reports shows that according to Martenstein (1926), fourteen of his sixteen cases of Lupus erythematosus were completely cleared up. Twelve of these were free from the disease for twelve (12) to fifty-five (55) months. Two relapsed in from thirty-eight (38) to forty-four (44) months respectively. Those cases which responded to treatment showed extremely slight scarring. Galewsky (1926) treated twenty-four (24) cases of all types of the condition with the following results: Ten (10) cured, eight (8) considerably improved, three (3) only slightly improved, one (1) unimproved, two (2) gave up the treatment before they were discharged. In several of the improved cases the treatment is being continued. Galewsky stated that his results were not as good as Martenstein's because three (3) of his cases were of the severe hyperkeratotic type which had been present for years, they had not been discharged.

Schamberg and Wright in 1927 gave abstracts of other papers on the gold treatment of Lupus erythematosus and showed their results with gold and sodium thiosulphate. They believed that this report was the first application of sodium and gold thiosulphate in the treatment of this condition. This report, however, overlooked the investigations of Galewsky (1924, 1926), and Jeanselme and Burnier (1926), who had previously used this drug. Schamberg and Wright state that they are still in doubt as to some of the technical features of the treatment, i.e., the dosage, frequency of administration, duration of treatment, etc. In high dosages, malaise and general depression were noted. In a few cases, albuminuria, urticaria, pruritus and scarlatiniform or polymorphous erythematosus eruption developed. They state that in one patient a fatal acute outbreak was stimulated. The summation of their case shows that the eruption disappeared in five cases, almost disappeared in six cases, improvement in twelve cases, and one patient died after receiving gold and sodium thiosulphate.

Our attention to this mode of treatment resulted from the investigations initiated by Throne (1925). Based on these clinical studies in which all modes of treatment had been applied, it was our desire to employ chemotherapeutic measures which would attack the disease from within. Radium, X-ray and  $CO_2$  snow had shown little progress in arresting the disease.

In our service a great many cases of Lupus erythematosus were seen and our attention was directed toward chemotherapeutic agents which could be administered intravenously. Much speculation had appeared in the European literature about undue toxicity and on this account our procedure was extremely cautious. In the beginning of our investigations, the initial dose was only 0.010 gram of Triphal per injection. The gold protein compounds of Schamberg had produced such severe reactions that these small doses were employed in spite of more accurate toxicity reports that had been experimentally obtained by us. Gradually, these doses were increased until the present mode of procedure which consists in the intravenous injection of 0.050 gram of Triphal as the initial dose, and increasing to 0.100 gram for each succeeding dose. These injections are given three times per week, if possible, good results are obtained with biweekly injections. The number of injections necessary to permanently arrest the condition varies with the duration of the disease and the extent of the pathological process.

The injections were all given intravenously and as a result of about fifteen hundred injections no painful infiltrations or disturbing reactions have been observed. The solutions of Triphal are prepared by sprinkling the contents of the ampule on the surface of cold, sterile, freshly distilled water. The product is readily soluble and gives a clear light yellow solution. Two and one-half cubic centimeters to five cubic centimeters of water are used for each injection without consideration of the dose. Occasionally, multiple doses are dissolved when several patients are ready for injections. However, caution is suggested in regard to the use of old solutions which become toxic and, in the case of gold and sodium thiosulfate, decomposition takes place, as indicated by the disagreeable odor of the solution. All injections should be made slowly.

The preparation employed by us in this series of patients was the sodium salt of aurous thiobenzimidazolecarboxylic acid. This preparation was selected as the most suitable on account of its low toxicity, stability in ampules and high tolerability. In the selection of this preparation a comparative study of the toxicity and gross pathological changes was made. Comparison of these results for Krysolgan, gold and sodium thiosulfate (Sanocrysin) and Triphal is given in the table below.

#### EXPERIMENTAL PROCEDURE

Healthy, male albino rats weighing 100 to 150 grams were employed. The rats were obtained from one source and were kept on a constant, well balanced diet (a mixture composed

of whole wheat flour, 53.5 per cent, corn meal, 10 per cent, skim milk powder, 33 per cent, calcium carbonate, 0.5 per cent, sodium chloride, 1 per cent, and cod liver oil, 2 per cent) for two weeks before the tests. They were fasted for from 16 to 20 hours immediately before the administration of the drugs when they were weighed and the doses administered per kilo body weight. The solutions of the drugs were prepared with freshly distilled water and were administered within one hour from the time of preparation. The concentrations of the solutions employed were as follows: Triphal, 2 per cent, gold and sodium thiosulfate, 1 per cent, and Krysolgan, 0.065 per cent. The injections were made into the saphenous vein at the rate of 0.1 cc solution every 12 to 15 seconds. A 1 cc syringe accurately graduated to 0.01 cc was employed. All animals that lived were observed for seven days when they were killed and carefully necropsied.

The toxicity tests were carried out by Dr C. W. Hooper.

It will be seen from the following tables that the maximal tolerated dose of Triphal for the albino rat is 120 milligrams per kilo body weight when injected intravenously. The maximal tolerated dose of gold and sodium thiosulfate is 60 milligrams per kilogram and the maximal tolerated dose of Krysolgan is 2 milligrams per kilogram. The gross pathologic lesions found at necropsy are also described.

The patients included in this report consist of the ambulatory group of individuals who attend the outpatient department of the hospital, with the exception of two who are noted in the case histories which follow. The fact must not be overlooked that the usual difficulty in keeping the patients in regular attendance was experienced in these cases. In spite of this, the results of treatment have been most gratifying. The total number of patients shown receiving treatment in our service is 58. These cases reported below consist of those termed as "cured" (complete arrest of the disease accompanied by complete disappearance of the lesions and the erythema) and those who have been under observation sufficiently long enough that a definite prognosis is available. All patients who are discharged are requested to return at two week intervals for observation.

The following histories illustrate our plan of attack.

No. 1 Mrs. Rose F., aged 50, showed typical patches on the cheeks below the eye lids. The duration of the disease was eight (8) years. Before treatment was instituted the patient was examined for focal infection. Five

## TOXICITY OF GOLD AND SODIUM THIOSULFATE

abscessed teeth were extracted. Triphal was given as follows: Oct 7 0.030 gm, Oct 14 0.080 gm. At the second visit decided improvement was noticed. Oct 21 and 28 No 4, 11 and 18, 0.100 gm was administered. Improvement had been progressive and at the date of the last injection no sign of the condition could be found.

This patient was shown by one of us (T) at the Brooklyn Dermatological Society and all the Members of that Society pronounced it a cured case. On December 13, an injection of 0.075 gm was given as a possible preventive against a recurrence. This patient, previous to the gold treatment had received all kinds of local and internal treatment except radium.

therapy Among other drugs she had been given many injections of arsphenamine In this case a total dose of 0610 gm was curative There has been no recurrence up to date

No 2 Marion McL, female, white, aged 16 years, was admitted for treatment Oct 25, 1926 The condition had begun on the face and scalp two years before In August, 1926, she had been badly sun-burned and the condition had spread rapidly and widely and when first seen the rash involved the nose, cheeks, forehead, chin, scalp, neck, shoulders, arms, forearms, and the dorsal surface of the hands and fingers On the forearms, hands and fingers some of the lesions were haemorrhagic The scalp was extensively involved, here, there were atrophic spots from old lesions and extensive alopecia from the spreading of the condition The patient was poorly developed and very ill She was admitted to the hospital and examined clinically and by X-ray for pulmonary tuberculosis No evidence of tubercular infection was found On admission she ran a septic type of temperature After a few days rest in bed her temperature became normal and gold treatment was instituted She received injections three times a week, 14 injections in all The first two injections were 0075 gm each and the remaining twelve were 0100 gm each The patient was discharged as cured on January 12 She was examined on February 2 and showed no trace of the condition Her general condition was much improved, her weight had gone up from 98 to 113 pounds, there had been a remarkable regrowth of hair, only the scarred spots were still bald Reference to this case will again be made

No 3 Mrs D R, white, Jewish, aged 42, was first seen June 11, 1924, when she showed a lesion on the side of the nose near the inner canthus of the left eye The lesion was irregularly round and about one inch in diameter It was markedly hyperkeratotic The patient had suffered with a rheumatoid arthritis for many years, otherwise she showed nothing abnormal There was a diabetic family history She was treated with CO<sub>2</sub> snow and radium but there was always a recurrence of the condition either in or at the edge of the scar caused by these agents

Gold treatment was instituted September 24, 1926, using very small doses On October 20, the dose had reached 0050 gm, this dose was repeated on October 22, October 25, 0075 gm was given On October 27 and 29 and on November 3, 8, 12, 15, 17, 22 and 28, December 15 and 22, 0100 gm were given Urine examination November 22 gave no evidence of kidney irritation On December 15 she appeared cured Examination February 7 showed no

signs of a recurrence In this case there was no reaction of any kind

No 4 Mrs M F, Hungarian, aged 35, was admitted for treatment June 11, 1926, for Lupus erythematosus involving practically the whole of the nose and the upper and lower eye-lids The condition had begun nine (9) months before She was put on gold treatment October 6, 1926 At first only very small doses were given On October 25, 0075 gm was given and on October 29, November 5, 10, 12, 17 and 19, the dose was 0100 gm On November 24, she showed an erythematovesicular rash on the forearms and hands For this condition Sodium Thiosulfate 05 gm in freshly prepared solution was given intravenously three times a week On December 15, all signs of this reaction had disappeared and she received Triphal of 0050 gm and on December 22, 29 and January 5 and 12, 0075 gm was given On January 12 she was pronounced cured No recurrence at present date

No 5 Mrs K S, white, American, aged 36, was admitted to the clinic on April 28, 1926 She showed a round lesion on the right cheek about one inch in diameter The duration of the lesion was one and a half years Gold treatment was begun on October 29, 1926 Injections of 0100 gm were given three times a week for fifteen injections She was pronounced cured on December 10, 1926 There has been no signs of recurrence up to February 7, 1927 In this case dental infection was found and this was cleared up before the gold treatment was begun In this case there was no reaction of any kind

No 6 L W, female, Jewish, aged 30, applied for treatment July 10, 1918, for Lupus erythematosus involving the nose, ears and the skin behind and below the ears The condition had been present at that date for four (4) years She received the usual treatment without any benefit and on December 1, gold treatment was instituted She received 0100 gm on December 1, 3 and 6 On December 6 she developed a papulo-vesicular rash on the arms, which spread and on December 8 became practically universal For this reaction she was given 05 gm sodium thiosulfate intravenously on December 8 and 13 On December 13 she had improved and gold injections of 0100 gm were given on December 13, 15 and 17 On December 31 she was pronounced cured Examination of this patient showed marked dental infection This was treated at the time of the reaction The total amount of Triphal given in this case was 0600 gm

No 7 L H, male, white, aged 24, admitted for treatment January 3, 1927 Duration of condition one and one-half years Location of lesions was as follows bridge of

nose, ears and the cheeks adjacent to the ears. The lesions were moderately infiltrated and hyperkeratotic. On January 3, he was given 0.050 gm and on January 7, 10, and 14, 0.075 gm. On January 21, he complained of moderate pruritus and on this date and on January 24 he was given 0.5 gm of sodium thiosulfate. The pruritus subsided rapidly and on January 31 he received 0.050 gm of Triphal. On this date he was well. There has been no recurrence.

No 8 Mrs M F, aged 65 years applied for treatment March 3, 1926. Duration 2 years. Practically the whole of the nose was involved. The type of the condition was hyperkeratotic. On December 22, gold treatment was commenced. She received on that date 0.100 gm and on the 27th and 29th, 0.075 gm. On January 1, 3, 10, 17, 21, 24, 26 and 31, 0.075 gm. Result—cured. Total dose, 0.775 gm.

No 9 D L, male, Italian, aged 31, admitted for gold treatment September 10, 1926, for extensive, thick, indurated, hyperkeratotic patches of Lupus erythematosus located on each cheek. The duration of these lesions was six (6) years. The early doses in this case as in others, were so small as to be negligible. On October 13, the dose had reached 0.060 gm. Up to February 2, 1927, he had received 25 injections in all and was cured. There was no reaction in this case.

No 10 J M, female, aged 31, was sent to the Department for Syphilis for a supposedly positive Wasserman. Her blood test here was persistently negative. She received many injections of arsphenamine, mercury and bismuth. This treatment had no effect on the lesions situated as follows on the face: one on the left side of the forehead, two on the right cheek, one on the malar eminence and the other on the cheek below this one. The lesions were of the indurated type. On January 5, she was transferred to the dermatological department, where a diagnosis of Lupus erythematosus of the indurated type was made and she was put on gold therapy. She received 0.075 gm of Triphal twice a week. On January 24, she complained of headache. This lasted only a few days and did not interfere with her treatment. She is well.

This case is especially interesting in view of the report of Ravaut and Bocage in *Annales de Dermatologie et de Syphiligraphie*, December, 1926, p. 658, in which they call attention to the frequency with which a positive Wassermann is found in patients suffering with Lupus erythematosus, and give the results of treatment of these patients with Novarsenobenzol. Ravaut and Bocage claim seven cures and four patients almost cured out of seven-

teen cases treated. It would seem from this that the toxæmia of syphilis as well as the toxæmia of other conditions, can at least predispose to the development of the condition which we call Lupus erythematosus and that in those cases showing syphilitic infection, as evidenced by a positive blood test, anti-syphilitic treatment is of value, but in those where there has been no infection, as seen in the above cases, this line of treatment is of no value. The same was seen in Case No 1, who had received many injections of arsphenamine without any benefit.

No 11 M G, female, aged 50. Lesion about three-quarters of an inch in diameter on the right cheek of five years duration. The lesion showed moderate infiltration, atrophy and hyperkeratosis. This patient received 0.100 gm of Triphal on the following dates: December 10, 13, 15, 17, 20, 22, 29 and 31, or a total dose of 0.900 gm. Result—cured.

No 12 S E, male, white, aged 35, applied for treatment on July 14, 1926, for a discoid patch of Lupus erythematosus situated on the right cheek below the eye. The patch was irregular in shape, about one and one-half inches long by three-quarters of an inch in width. It had been present five months and showed atrophy, infiltration and hyperkeratosis. The Wasserman test was negative. He was put on gold treatment in September and until October 18, the doses were negligible. On this date he was given 0.075 gm. After this he received injections three times a week of from 0.075 gm to 0.100 gm, until January 12, 1927. On December 15, he was cured, and at present showed no signs of any activity in the lesion.

No 13 E Z, female, Jewish, aged 15. Duration of condition one year. Location of the rash was on the nose and cheeks. Examination showed dental infection which was cleared up before treatment was instituted. On October 22, she received 0.050 gm of Triphal. On November 1, 3, 5, 8, 10, 15, 17, 22 and 26, 0.100 gm were given. On December 1, 8, and 15, the same amount was injected. On December 27, she received 0.050 gm and on January 3 and 17, 0.075 gm. On January 3, she seemed cured. The injection on the 17th and another on February 7 were given to prevent a possible recurrence. On February 18, there was no sign of the condition left and the amount of scarring was extremely small. In this case there was no reaction.

No 14 B B, white, female, aged 40, showed a lesion on the right cheek about an inch in diameter. The duration of this lesion was six months. She received 0.100 gm of Triphal on November 19, 24, 26 and 29, December 1, 3 and 22 and on January 7 she received 0.075 gm. She was cured. Total dose, 0.775 gm.

No 15 A G, male, white, aged 39 Duration of condition two and one-half years The nose showed six isolated spots about the size of a ten cent piece and on the left malar region there was one lesion the size of a twenty-five cent piece All lesions were hyperkeratotic and all showed atrophy The patient showed dental infection This was cleared up and Triphal was given as follows January 10, 1927, 0.050, January 21, 0.075, January 28, February 4, 11, 18 and 26, 0.100 gm On February 4 the lesions were less red, the scaling had subsided and the infiltration was beginning to be absorbed At present the patient is well There was no reaction of any kind in this case

No 16 A N, female, aged 35, showed two spots on her right cheek when she applied for treatment on October 22, 1926 These spots were about the size of a twenty-five cent piece They were hyperkeratotic and showed atrophy Her history showed that she had suffered from a rheumatoid arthritis The duration of the skin condition was sixteen months She was put on Triphal and received three injections a week until January, when they were cut down to twice a week On February 14, she was very much improved and on March 5 she was practically well On the latter date there was no scaling and practically no redness left No reaction of any kind in this case This case was discharged as cured and returns for observation

No 17 R R, aged 40, female, white, was admitted November 12, 1926 She showed extensive involvement of the nose with a typical discoid type of the disease which had been present for six (6) years She was put on gold treatment on November 15, and on that date and on November 22, 26, and 29, and on December 3, 6, 10, 15, 17 and 20, she received 0.100 gm of Triphal, on December 31 and January 7, 0.075 gm, on December 20 she was much improved She complained of headache after some of the injections, but they were not sufficiently severe to interrupt the treatment This patient showed dental infection At present patient is well

No 18 Mrs L F, aged 32, showed the butterfly type of the condition which had been present for eight years The scalp was also involved She was put on gold therapy October 6 On October 18, the dose had been increased to 0.050 gm and on October 29 the amount was raised to 0.100 gm Following this dose she developed a reaction in the form of an erythematopapular rash on the flexor surfaces of the arms and forearms This rash spread to the trunk and thighs and legs It was intensely pruritic The lesions disappeared with the appearance of the reaction For the reaction she was given sodium thio-

sulfate 0.5 gm intravenously in freshly prepared solution On February 7, the reaction had subsided but there was a recurrence of the Lupus in the form of very moderate scaling and erythema This patient showed dental infection which was not cleared up until her reaction developed She will be given further Triphal injections

No 19 John B, aged 41 Duration of the Lupus erythematosus was five years The location of the lesions was on the nose and right cheek He had been treated with radium without any benefit He showed severe dental infection and was very reluctant to have this treated and only consented to have the infected teeth extracted when he developed a moderate pruritus on account of which the Triphal injections were discontinued and sodium thio-sulfate was given His first gold treatment was given on October 29 After five injections of 0.100 gm each, given every third day, the reaction developed On March 4, he began to show improvement After completion of the dental work the injections of Triphal were resumed and at this date the patient is well

No 20 Tony V, male, aged 50, applied for treatment on April 29, 1925 He presented a hyperkeratotic type of the condition with extensive involvement of the nose and cheeks On October 22, 1926, gold therapy was started On this date and on October 27, November 1, 5, 8, 10, 15 and 29, and December 3, 8 and 20, he was given 0.100 gm On January 7, 10, the dose was 0.075 gm On account of an attack of influenza he was unable to come to the clinic for several weeks On his return on March 5, he was very much improved Treatment is being continued and the prognosis for a complete cure in his case is good

No 21 Jos F, male, aged 31, onset of condition, 1924, location of lesions was on nose, cheeks and lower lip All showed marked scaling, infiltration and in places atrophy Gold treatment was instituted on January 21 with injections twice a week of 0.075 gm On February 14 he showed a great deal of improvement and at present he is almost entirely cured He showed dental infection, three teeth were extracted at the commencement of treatment He had no reaction Case discharged as cured

No 22 D L, male, white, aged 31 Duration of condition two and one-half years Over the malar eminence a rounded lesion appeared about one and a half inches in diameter, on the right cheek in front of the ear a patch approximately two and a half by one inch, and on the left cheek in front of the ear there was a lesion three and a half by one and a half inches All lesions were markedly indurated,

hyperkeratotic and showed considerable atrophy

On October 13 and 18 he received 0.060 gm of Triphal, on the 20th and 25th, 0.050, on the 27th and 29th, 0.100 gm. On November 1, 3, 8, 10, 17 and 19, 0.100 gm, on the 22nd, 0.075 gm, on November 24 and 29, December 1, 3, 8, 15, 24, 29 and 31, 0.075 gm, January 2, 19 and 26, February 2, 14 and 23, 0.075 gm. Improvement began in the latter part of November, it has been slow but persistent. From the above dates it can be seen that since December 2, he came very irregularly for treatment. On February 23, he showed very little scaling. The erythema had subsided considerably and the infiltration was being absorbed. Prognosis as to cure is good.

The following cases were given this type of treatment, but discontinued their treatment before a cure was obtained.

No 23 H M, male, aged 25, admitted for treatment November 1, 1926, for lesions on the right ear and lower lip which had been present for three years. He received injections on November 1, 3, 15 and 22, December 1, 8, 15, 22 and 29, January 12 and 19. Since the last date he has not been seen. A letter from him received March 4, states that he is much improved.

No 24 Jos S, male, aged 18, showed a lesion on the right cheek about two by one and a half inches in size. The lesion was very keratotic and showed atrophy. It had been present for three and a half months. He had dental infection. He was put on gold treatment November 10. His attendance at the clinic during November, December and January was very irregular. On January 31 he showed marked improvement.

No 25 Wm G, male, aged 31, was admitted November 25, 1926, for Triphal. He showed involvement on the left ear and right cheek. He received up to January 7, eleven injections of 0.100 gm each. He has not been seen since January 7.

In the series of twenty-five cases which have had a course of treatment gold reactions in a mild form were observed in cases 4, 6, 8 and 10. These reactions did not materially interfere with the plan of treatment. The blood chemistry of these patients showed the typical changes in sugar and chloride content as observed in heavy metal poisoning. In each instance sodium thiosulfate in freshly prepared solution brought about the detoxification of the individual in a comparatively short time. The first symptom of reaction is pruritus and the gold treatment should be discontinued at once. It is our belief that the use of sodium thiosulfate enterically greatly increases the tolerance. Intravenous injections of freshly prepared sodium thiosulfate solutions should

be given every third day until all signs of reaction disappear. The sodium thiosulfate in this type of reaction is just as specific as in arsenic reactions and eczema.

#### FOCAL INFECTION AND REACTION

While no claim is made as to the causal relationship of focal infection and Lupus erythematosus, its very frequent association cannot help being striking. The very constant recurrence of the condition with older methods of treatment, especially in those cases which were treated with CO<sub>2</sub> snow and radium in whom focal infections were not treated before radical treatment was instituted and the absence of these recurrences, as was shown by one of us (Throne, 1925). It might be added that some of the cases included in that study have been seen recently and are still free from the disease. (These cases were treated with radium by Dr A. Schuyler Clark.) It is believed that the lack of reactions and the rapidity of a cure will be greatly enhanced by first a careful examination for any evidences of such infection and its radical removal. A comparison on the histories of patients Nos 1 and 5, in whom such infection was found and treated and who responded rapidly to the gold injections, with case No 6 which showed extensive dental infection and which had the most severe reaction observed in the whole series. This reaction can at least be compared to the reaction of arsphenamine which Stokes (1923) believes is most liable to occur in syphilitics who have a streptococcic infection.

Chemically, Sanocrysin, gold and sodium thiosulfate, and crisalbine are all of approximately the same composition, that is, aurous salts of sodium thiosulfate. Varying amounts of gold are found in this group. The exact composition is not known although the formula  $3 \text{Na}_2\text{S}_2\text{O}_3 \cdot \text{Au}_2\text{S}_2\text{O}_3 \cdot 4 \text{H}_2\text{O}$  is ascribed to this group. For convenience, the calculations of gold found fits this configuration. The gold content varies from 15 to 37.5 per cent gold.

Krysolgan is 4-amino-2-aurio thiophenol carbonic acid sodium. The gold content is 44 per cent. A comparison of the toxicity of the various gold preparations is presented, showing the gross pathology in the experimental animal.

In this report a series of cases is referred to who have not yet received a full course, and they will be reported later.

In our series of patients five (5) showed a reaction. Of these five, three (3) had focal infection which was not cleared up until after the reaction developed. In two (2) focal infection was not found. In six (6) other patients focal infection was found and treated before instituting gold therapy. It is very interesting to note that not one of the last

No 15 A G, male, white, aged 39 Duration of condition two and one-half years The nose showed six isolated spots about the size of a ten cent piece and on the left malar region there was one lesion the size of a twenty-five cent piece All lesions were hyperkeratotic and all showed atrophy The patient showed dental infection This was cleared up and Triphal was given as follows January 10, 1927, 0.050, January 21, 0.075, January 28, February 4, 11, 18 and 26, 0.100 gm On February 4 the lesions were less red, the scaling had subsided and the infiltration was beginning to be absorbed At present the patient is well There was no reaction of any kind in this case

No 16 A N, female, aged 35, showed two spots on her right cheek when she applied for treatment on October 22, 1926 These spots were about the size of a twenty-five cent piece They were hyperkeratotic and showed atrophy Her history showed that she had suffered from a rheumatoid arthritis The duration of the skin condition was sixteen months She was put on Triphal and received three injections a week until January, when they were cut down to twice a week On February 14, she was very much improved and on March 5 she was practically well On the latter date there was no scaling and practically no redness left No reaction of any kind in this case This case was discharged as cured and returns for observation

No 17 R R, aged 40, female, white, was admitted November 12, 1926 She showed extensive involvement of the nose with a typical discoid type of the disease which had been present for six (6) years She was put on gold treatment on November 15, and on that date and on November 22, 26, and 29, and on December 3, 6, 10, 15, 17 and 20, she received 0.100 gm of Triphal, on December 31 and January 7, 0.075 gm, on December 20 she was much improved She complained of headache after some of the injections, but they were not sufficiently severe to interrupt the treatment This patient showed dental infection At present patient is well

No 18 Mrs L F, aged 32, showed the butterfly type of the condition which had been present for eight years The scalp was also involved She was put on gold therapy October 6 On October 18, the dose had been increased to 0.050 gm and on October 29 the amount was raised to 0.100 gm Following this dose she developed a reaction in the form of an erythematopapular rash on the flexor surfaces of the arms and forearms This rash spread to the trunk and thighs and legs It was intensely pruritic The lesions disappeared with the appearance of the reaction For the reaction she was given sodium thio-

sulfate 0.5 gm intravenously in freshly prepared solution On February 7, the reaction had subsided but there was a recurrence of the Lupus in the form of very moderate scaling and erythema This patient showed dental infection which was not cleared up until her reaction developed She will be given further Triphal injections

No 19 John B, aged 41 Duration of the Lupus erythematosus was five years The location of the lesions was on the nose and right cheek He had been treated with radium without any benefit He showed severe dental infection and was very reluctant to have this treated and only consented to have the infected teeth extracted when he developed a moderate pruritus on account of which the Triphal injections were discontinued and sodium thiosulfate was given His first gold treatment was given on October 29 After five injections of 0.100 gm each, given every third day, the reaction developed On March 4, he began to show improvement After completion of the dental work the injections of Triphal were resumed and at this date the patient is well

No 20 Tony V, male, aged 50, applied for treatment on April 29, 1925 He presented a hyperkeratotic type of the condition with extensive involvement of the nose and cheeks On October 22, 1926, gold therapy was started On this date and on October 27, November 1, 5, 8, 10, 15 and 29, and December 3, 8 and 20, he was given 0.100 gm On January 7, 10, the dose was 0.075 gm On account of an attack of influenza he was unable to come to the clinic for several weeks On his return on March 5, he was very much improved Treatment is being continued and the prognosis for a complete cure in his case is good

No 21 Jos F, male, aged 31, onset of condition, 1924, location of lesions was on nose, cheeks and lower lip All showed marked scaling, infiltration and in places atrophy Gold treatment was instituted on January 21 with injections twice a week of 0.075 gm On February 14 he showed a great deal of improvement and at present he is almost entirely cured He showed dental infection, three teeth were extracted at the commencement of treatment He had no reaction Case discharged as cured

No 22 D L, male, white, aged 31 Duration of condition two and one-half years Over the malar eminence a rounded lesion appeared about one and a half inches in diameter, on the right cheek in front of the ear a patch approximately two and a half by one inch, and on the left cheek in front of the ear there was a lesion three and a half by one and a half inches All lesions were markedly indurated,

eleven gave a positive complement fixation test for tuberculosis Sladkowitzsch (1926) investigated 272 cases of Lupus erythematosus in the Moscow Lupusorium and could find no proof of a tubercular origin of the condition, 106 of these cases were examined by Dr V V Vladimírsky, the consultant of the Lupusorium, and only 7 cases showed a more or less active tuberculosis Of 135 cases tested with tuberculin, 105 gave a negative reaction even to 12½ per cent tuberculin, while 98 per cent of cases of Lupus vulgaris and of the tuberculids gave a positive reaction with 2½ and 5 per cent solutions of tuberculin Galewsky (1926) says "Recent data and the differences with which Lupus erythematosus reacts to gold, leads me more and more to agree with the opinion of Zumbusch that Lupus erythematosus does not have any one simple cause, but there must be other factors in addition to its relation to tuberculosis"

#### SUMMARY

Twenty-five (25) cases are reported after one course of treatment, ten (10) males and fifteen (15) females The youngest patient was fifteen (15) years of age and the oldest was sixty-five (65) The duration of the condition was from five (5) months to eight (8) years

Examination of patients at present time indicates that cures were obtained in seventeen (17) cases Five cases show considerable improvement They are still under treatment and the prognosis for a cure in them is good Three (3) discontinued treatment voluntarily One of these has written that he is improved If we leave out these three cases, a cure has been obtained in 77.2 per cent of the cases treated

In no case was the reaction sufficient to cause any alarm either to ourselves or to the patients

In gold therapy, as illustrated by Triphal, a method of treatment for Lupus erythematosus has been established which promises to be specific

Reactions are more liable to occur in the presence of focal infection Patients should be examined for focal infection, and if this is present, it should be removed before gold treatment is instituted If reactions occur, sodium thiosulfate in freshly prepared solution is specific for them as it is for the toxæmias from arsenic, mercury and lead

Triphal if used with ordinary care is a safe and effective preparation in the treatment of Lupus erythematosus and should be treated on this basis because of its comparatively low toxicity and chemical stability, and ready solubility It is also a preparation that is well tolerated

Gold injections cause the same changes in the blood picture as do arsenic (both the arsphenamine and the pentavalent arsenical compounds) mercury and lead, that is to say, there is a marked reduction in the chloride content of the blood stream and a similar high sugar value

The comparative toxicity of the various gold preparations is given in the tables

Clinical study of 58 cases has been carried out in this investigation

group of patients showed the least sign of any trouble from the treatment, and in addition, the course of treatment in most of them was considerably shortened

Rickman (1924) from a clinical point of view, confirms these findings in his studies on the treatment of tuberculosis. The author states that the injuries seen after the other gold preparations are not observed after Triphal

The use of the powder and freshly prepared solutions is emphasized by Gori and Voigt (1926) who observed reactions following the use of the drug put up in solutions of varying age. Insofar as reactions are concerned, these authors in their conclusions point out the advantage of using freshly prepared solutions of the gold preparations. As a result of our own experiences, a freshly prepared solution of sodium thiosulfate is also more efficacious

Bruhns states that three fatal cases following the administration of Krysolgan have been seen—his own and one reported by Stein (Goerlitz) communicated by Martenstein, and one by Havenstein

Bruhns' case was a patient aged 61, internal examination was negative, the urine was negative for albumin and sugar. The duration of the disease was four months. The diagnosis was Lupus erythematosus acutus, but for six weeks there was no tendency to spread and the patient was free from fever. Following the injection of 0.001 gm of Krysolgan a severe focal reaction developed with a marked oedema which involved the larynx and trachea. Anuria developed after about 20 hours and 44 hours after the injection the patient died. Catheterized specimen of urine showed casts and leucocytes

Stein's case was one of Lupus erythematosus, Krysolgan was injected in doses of 0.05, 0.1 and 0.1 gms at intervals of 6 and 9 days. Ten days after the last injection a stomatitis developed. This in turn, was followed by a mild exanthem accompanied by albuminuria, anuria and exitus. Before treatment the urine of this patient was free of albumin. no autopsy was made

Havenstein's case was one in which there was a lung and laryngeal tuberculosis, and doses of 0.05 and 0.10 gms 14 days apart was followed by a severe reaction accompanied by fever (38.5). On the eighth day meningitis developed and eight days later the patient died

#### METHOD OF TREATMENT

In the beginning of our work with Triphal very small doses (0.010 gram) were used. When the toxicity tests had been done this dose was increased to 0.100 gram, the injections being given three times a week

There is no absolute dose for all cases. Each

case must be treated individually. The cases showing only superficial involvement seem to respond to small doses, about 0.075 gram, twice a week. Two of the cases included in this report received only one injection of 0.100 gram a week. In old, thick, indurated cases showing excessive hyperkeratosis, the dose must be larger. Our experience indicates that at least 0.400 gram per week should be used on this type of case

In some of our cases, the Triphal injection has been supplemented by giving tablets of gold and sodium chloride one-twentieth of a grain each, three times a day, after meals. This has seemed to be of considerable value and is especially indicated where it is impossible to see the patient more than once or twice a week

#### CONTRAINDICATIONS

Advanced kidney and liver lesions seem to be the only absolute contraindications to this type of therapy

Focal infections should be cleared up before instituting treatment. Examination of the histories of the patients included in the above shows clearly that in those patients whose pus foci were attended to before gold treatment was given, there was no reaction and the duration of treatment was materially shortened

Galewsky cautions in regard to the use of gold in cases which had a connection with light sensitization. Case No 2 was of this type but showed no reaction

Response of patients suffering with skin conditions of known tubercular origin

Three cases of Lupus vulgaris were given this line of treatment. They were not benefited

One case of tuberculosis verrucosa cutis did not respond

Two cases of erythema induratum did not respond

One case of Angio Lupoid did not respond

Two cases of papulo-necrotic tuberculids did not respond

One case of Lupus Pernio, Besnier type, did not respond

We do not mean to state that this condition is unquestionably tubercular. The failure of conditions of known tubercular origin to respond to this type of therapy is an added support of the conclusions of Throne (1925) who could not find any relationship between Lupus erythematosus of the chronic discoid type and tuberculosis. In his study he found in a series of thirty patients suffering with Lupus erythematosus a positive blood complement-fixation for tuberculosis in only four cases and these four cases had demonstrable tubercular infection, on the other hand, in twelve cases of known tubercular origin,

Societies have not reported them. The meetings of the District Branches in the Fall of 1926 revealed some excellent work done. The meetings of the Sixth District Branch in Oswego on September 21, 1926, gave out the first news that the Editors received about the public health nursing work conducted by the Medical Society of Tioga County. This work was unique and original, and was worthy of developing in any County. News of it should have come to the Journal directly from the Tioga County Medical Society.

The news of the child welfare clinics conducted by the St. Lawrence County Medical Society came first to the notice of the Journal at the meeting of the Fourth District Branch on October 1, 1927, at Plattsburg.

*When to Report* When and how shall the Secretary report the public health activities of his County Society? A committee in charge of an activity will at least report progress to a meeting of the Society. This brief report affords the opportunity of the Secretary to describe the plans and activities of the committee. While they may seem commonplace to the members of the Society, they are of deep interest to the leaders of the State Society and

of other County Societies who are working along similar lines.

*The Form of a News Item* The principal point regarding a news item is that it shall contain authentic information. It may be in the form of a newspaper clipping, or rough notes, or it may be a finished paper. The Editor will put it in shape if only he gets the news. The important point is "Send the news."

*Reporting and Editing* Every editor's office carries on two activities:

- 1 Reporting, or getting news
- 2 Editing, or preparing it for printing

While the New York State Journal of Medicine was published monthly, its Editorial Staff could also do reportorial work in the field, but since it has been issued twice a month, the Editor has not had time to do much reportorial work. The Journal must therefore depend on the secretaries of the County Societies for news of their organizations.

Just as the physicians of New York State have come to know one another through their County Societies, so may the County Societies come to know one another through the news columns of the New York State Journal of Medicine.

## THE USE AND MISUSE OF IODINE IN THE TREATMENT OF TOXIC GOITER\*

By EMIL GOETSCH, M. D., BROOKLYN, N. Y.

Studies of Thyroid Disorders

THE dangers in operations upon exophthalmic goitre are familiar to all experienced surgeons. Aside from the immediate danger of operative hemorrhage one commonly feared the toxic postoperative reaction lasting usually from thirty-six to forty-eight hours, and characterized by extreme restlessness, excitability, temperatures reaching as high as 105°-106°, pulse elevation to 180 or more, and finally by delirium, coma and even death. This postoperative period was one of great anxiety to the surgeon. To guard against this dangerous reaction it was necessary to resort to several palliative measures, which were planned to improve the patient to such an extent that the resection operation could be carried out safely and with the least postoperative distress. Thus long periods of rest were often required. Preliminary X-ray treatments were sometimes given and preliminary ligations of the thyroid arteries were performed, the idea being to diminish the activity of the gland. The general condition of the patient was thereby improved sufficiently to render thyroidectomy safe. Stage operations became very general in treating patients with active

exophthalmic goitre. The results were strikingly good. The great disadvantage was, however, that patients were submitted to many therapeutic measures including two or more operative procedures. I have in mind an extremely toxic and emaciated patient who came to me three years ago with a huge vascular exophthalmic goitre, upon whom I performed five stage operations, three ligations at different times and two separate lobectomies three months apart, before a cure was finally established.

Postoperative hyperthyroidism was rarely feared after operation for adenomatous goitre and therefore ligations were rarely resorted to. I think I have performed ligations in adenomatous goitre in not more than two or possibly three cases. The arteries are, as a rule, small in adenomatous goitre and therefore little good can be expected from ligation.

The effect of iodine in causing hyperplastic thyroid tissue to revert to the inactive colloid type of gland had been described by Marine many years ago. Plummer in 1923 originated the intensive preoperative iodine treatment of exophthalmic goitre. It was found that in giving massive doses of iodine to the patient with exophthal-

## PUBLICITY FOR COUNTY MEDICAL SOCIETIES\*

By FRANK OVERTON, M D, PATCHOGUE, N Y

*Object* The object of this talk is to secure news items from the County Medical Societies for publication in the New York State Journal of Medicine. The Journal is the official organ of the Medical Society of the State of New York, of its eight District Branches, and of its sixty County Medical Societies.

The County Medical Society is the fundamental unit of the organizations of physicians, for it deals with the individual physicians. The policy of the New York State Journal of Medicine is to inspire and assist the doctors of the State to practice the best type of scientific medicine in all fields—private practice, public health, and civic medicine.

The Journal gives a prominent place to the activities of the County Medical Societies, and has utilized the news from whatever source it came. The principal source of news is the County Society itself, but one third of the items of the societies come from other sources. The number of county society news items that have appeared in the Journal from January 1, 1924 to September 1, 1927 have been one hundred and ninety-five. The three societies sending the greatest number are Bronx, 18, Queens, 15, Otsego, 10. Seven have sent none at all: Chemung, Madison, New York, Rensselaer, Tioga, Warren and Wyoming. Sixteen counties have sent one each.

Deducting all these, there are left 34 counties which have sent 136 items, or an average of four each, or one in each year.

The lessons that may be drawn from these figures may be pessimistic or optimistic, depending on one's temperament.

The figures inspire a considerable degree of satisfaction and optimism when they are compared with the County Society items in other State Medical Journals. There is disappointment when one considers the valuable items which have not been reported—for example, the public health nursing activities of the Tioga County Medical Society.

*Kinds of Items Desired* The managers of the Journal wish to report the activities of the County Medical Societies. What are those activities?

The scientific session is the oldest activity of a county society, and it is still the most essential and fundamental. It was formerly the only activity of many societies. The files of our Journal of twenty-five years ago show that nearly all the County Societies limited their activities to the scientific program consisting of the reading of formal papers. But about the

year 1924 there began a spontaneous broadening of the field of the Societies of the State, the Districts, and the Counties. When the Journal was reorganized in 1924, its Executive Editor made surveys of 30 counties which were published in the Journal from July, 1924, to November 1, 1925. The officers of many Societies were considerably embarrassed over their inability to record any activity of their Societies besides the scientific programs, but the fields have broadened with a rapidity which is almost startling. The new fields of activity may be classed under three headings:

- 1 Educational
- 2 Social
- 3 Public health

Practically every County Society has done an excellent piece of work in some one of these lines of activity. While no Society has attained its ideals in all lines, yet every Society has done something in a better way than any other Society has done it. The Journal seeks the news items regarding what has actually been done. The Journal has missed many important items simply because no one has informed the Editors about them.

*Educational Work* Nearly every County has engaged in some form of educational work under the stimulus of the Committee on Education and Public Health of the State Society. The annual report of the Committee reveals a range of activities that is far wider than are indicated by the reports from the individual counties.

Send in the reports of the educational activities of your County Societies.

*Social Activities* The County Societies have inspired doctors with a friendliness that was unknown a generation ago. Dinners and outings are now important functions of County Societies. Especially valuable are the dinners in honor of physicians who have been in practice for half a century. The reports of some of these meetings reach the Journal, but more are left unnoticed. Send them along.

*Public Health* County Medical Societies no longer confine their activities to their own members, but they are discharging the duties which the Medical Profession owes to the public. The public health activities of a County Society usually develop gradually, and often take unexpected turns. Physicians are reluctant to say what great things they are going to accomplish, and they hesitate to claim a great importance for an activity that is only a few weeks old. However, a number of excellent pieces of public health work have gone unrecorded because the officers of the County

\* Read before the Conference of the Secretaries of the County Medical Societies of New York State, held in Albany on September 15, 1927.

Societies have not reported them. The meetings of the District Branches in the Fall of 1926 revealed some excellent work done. The meetings of the Sixth District Branch in Oswego on September 21, 1926, gave out the first news that the Editors received about the public health nursing work conducted by the Medical Society of Tioga County. This work was unique and original, and was worthy of developing in any County. News of it should have come to the Journal directly from the Tioga County Medical Society.

The news of the child welfare clinics conducted by the St. Lawrence County Medical Society came first to the notice of the Journal at the meeting of the Fourth District Branch on October 1, 1927, at Plattsburg.

*When to Report* When and how shall the Secretary report the public health activities of his County Society? A committee in charge of an activity will at least report progress to a meeting of the Society. This brief report affords the opportunity of the Secretary to describe the plans and activities of the committee. While they may seem commonplace to the members of the Society, they are of deep interest to the leaders of the State Society and

of other County Societies who are working along similar lines.

*The Form of a News Item* The principal point regarding a news item is that it shall contain authentic information. It may be in the form of a newspaper clipping, or rough notes, or it may be a finished paper. The Editor will put it in shape if only he gets the news. The important point is "Send the news."

*Reporting and Editing* Every editor's office carries on two activities:

1. Reporting, or getting news
2. Editing, or preparing it for printing

While the New York State Journal of Medicine was published monthly, its Editorial Staff could also do reportorial work in the field, but since it has been issued twice a month, the Editor has not had time to do much reportorial work. The Journal must therefore depend on the secretaries of the County Societies for news of their organizations.

Just as the physicians of New York State have come to know one another through their County Societies, so may the County Societies come to know one another through the news columns of the New York State Journal of Medicine.

## THE USE AND MISUSE OF IODINE IN THE TREATMENT OF TOXIC GOITER\*

By EMIL GOETSCH, M. D., BROOKLYN, N. Y.

Studies of Thyroid Disorders

THE dangers in operations upon exophthalmic goitre are familiar to all experienced surgeons. Aside from the immediate danger of operative hemorrhage one commonly feared the toxic postoperative reaction lasting usually from thirty-six to forty-eight hours, and characterized by extreme restlessness, excitability, temperatures reaching as high as 105°-106°, pulse elevation to 180 or more, and finally by delirium, coma and even death. This postoperative period was one of great anxiety to the surgeon. To guard against this dangerous reaction it was necessary to resort to several palliative measures, which were planned to improve the patient to such an extent that the resection operation could be carried out safely and with the least postoperative distress. Thus long periods of rest were often required. Preliminary X-ray treatments were sometimes given and preliminary ligations of the thyroid arteries were performed, the idea being to diminish the activity of the gland. The general condition of the patient was thereby improved sufficiently to render thyroidectomy safe. Stage operations became very general in treating patients with active

exophthalmic goitre. The results were strikingly good. The great disadvantage was, however, that patients were submitted to many therapeutic measures including two or more operative procedures. I have in mind an extremely toxic and emaciated patient who came to me three years ago with a huge vascular exophthalmic goitre, upon whom I performed five stage operations, three ligations at different times and two separate lobectomies three months apart, before a cure was finally established.

Postoperative hyperthyroidism was rarely feared after operation for adenomatous goitre and therefore ligations were rarely resorted to. I think I have performed ligations in adenomatous goitre in not more than two or possibly three cases. The arteries are, as a rule, small in adenomatous goitre and therefore little good can be expected from ligation.

The effect of iodine in causing hyperplastic thyroid tissue to revert to the inactive colloid type of gland had been described by Marine many years ago. Plummer in 1923 originated the intensive preoperative iodine treatment of exophthalmic goitre. It was found that in giving massive doses of iodine to the patient with exophthal-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y. May 11, 1927.

mic goitre just before operation, the symptoms and signs were promptly ameliorated. The patient became far less nervous and the danger of postoperative hyperthyroidism was practically eliminated. Lugol's solution was accordingly administered in doses of ten to fifteen minims three times a day for a period of a week or ten days preceding operation.

In considering the effects of these massive doses of iodine we might first consider the changes produced in the thyroid itself. The gland commonly swells, becomes firm or even hard, due to the rapid accumulation of colloid in the glandular acini. The vascularity often diminishes in a most striking way. The thrills and bruits, commonly found over the superior arteries and the gland itself, often disappear entirely. It is interesting to speculate how this is brought about. Suffice it to say that to some it appears that this change results from the increased firmness and swelling of the gland. These factors and the increased tension of the capsule make it difficult for the immense supply of blood to find its way through the gland. The blood is, as it were, squeezed out of the gland by pressure upon and collapse of the vascular spaces. The increased size of the gland is noticeable to the patient, who may complain of a sense of choking or difficulty in swallowing. Microscopically the exophthalmic gland with its characteristic hyperplasia is found to have strikingly reverted to the appearance of a simple colloid goitre. This change is interpreted as a resting or storage phase of the thyroid gland. Furthermore, I have found that the mitochondria, which are interpreted as indices of cellular activity, become smaller and much fewer in number and lose considerable of their staining affinity. All these changes are believed to be evidence of the conversion of the active hyperplastic thyroid to the resting or storage gland. The secretory activity of the thyroid cells is thus inhibited. These pathological changes offer to my mind a far more satisfactory explanation of the lull in the disease than the theory that iodine, intensively administered, is combined with and renders innocuous the supposedly unsaturated iodine molecule of thyroid secretion which is otherwise unusually toxic. It is in the stage of rest and storage of colloid and possibly thyroxin that operation is most safely undertaken. Following this quiescent period which is unfortunately only transient and as a result of the storage of iodine, the secretory activity is gradually resumed and eventually greatly accelerated, the colloid disappears, the gland shrinks in size and the vascularity increases. Thus in four to six weeks after iodine is discontinued we may actually have a marked exacerbation of the disease.

In the patient with exophthalmic goitre treated for the first time intensively with iodine, we find a marked decrease in the nervousness, tachycardia

and throbbing. There is improvement in appetite with increased weight together with a general feeling of well-being. The metabolic rate at times falls as much as forty to sixty points, and there is furthermore a diminished hypersensitivity to adrenalin. The patient is consequently a far better operative risk and dangerous postoperative reactions are rare indeed. Stage operations except in those patients promiscuously treated with iodine are rarely necessary, and the mortality following extensive double resection operations has in experienced hands become almost a negligible factor. It is most gratifying to see how comfortable the convalescence has become. There is no unusual nervousness or restlessness, only slight elevation of temperature and pulse and very little if any nausea and vomiting. The patient takes nourishment promptly and recovery is rapid. Acetonuria is seldom seen or when it does occur is slight and transient whereas formerly it occurred frequently and often lasted three to five or six days.

There is one important exception to this otherwise startling story of the effect of intensive iodine therapy and that is, that in cases which have received iodine over varying periods of time, the further intensive treatment either has relatively little or no effect. Small doses of iodine are apt to be promptly stimulating whereas the larger doses produce a temporary remission of symptoms only to be followed by relapse or even crisis in three to six or eight weeks later. Frequently patients are aware of the secondary increase of symptoms and often voluntarily cease taking iodine. They may leave their physicians and seek further medical advice or when in a serious state of acute, practically uncontrollable hyperthyroidism come to the surgeon. If iodine is now discontinued the acute symptoms are prolonged for a period of weeks or even months before spontaneous improvement occurs. Rather than to prolong this period of acute suffering one is forced to continue the intensive iodine treatment, producing thus a state of chronic hyperthyroidism, which though tolerable to the patient is in no way comparable to the results obtained when iodine is given for the first time. Consequently, preliminary ligations may be necessary inasmuch as the condition may not allow the radical resection operation in one stage. On the other hand, should a single lobectomy be performed, one has a choice of two procedures. One may choose to discontinue the administration of iodine whereupon almost invariably a long period of acute hyperthyroidism results due to the excessive secretion of thyroxin elaborated from the iodine store in the opposite lobe. On the other hand, one may be forced to hold the patient in a state of chronic hyperthyroidism by continued iodine treatment. A second operation

for removal of the remaining lobe is usually necessary

I may cite briefly a single unfortunate experience during the past year with a case of exophthalmic goitre which had been given large amounts of iodine by mouth and by injection over a period of two years. She came to me in a state of extreme hyperthyroidism. She was highly nervous, tremulous, irritable and dyspnoeic. The pulse was 144. She was bordering on what might be called crisis. Rest and sedatives were prescribed over a period of five weeks. Thereupon, ligations of the superior thyroid arteries were performed at separate times. She was watched and treated for a period of three months or more. The improvement was only moderate. Finally when all hope for further improvement was abandoned and it was evident that some further surgical procedure would have to be done, she was given intensive iodine treatment and even a few doses of sodium iodide intravenously. It was impossible to reduce the basal metabolic rate below +47. The thyroid became larger and harder, indicating that the iodine had had the usual local effect. At operation a large, hard, gland was doubly resected with considerable difficulty. In spite of all the precautions exercised, namely, preliminary ligations, rest in bed and apparently adequate iodimization, the operation was followed by an acute hyperthyroid crisis. Death followed in forty-eight hours. This case illustrates the dangers the surgeon may meet in operations on exophthalmic goitre patients previously indiscriminately iodimized. The usually safe operation of double lobectomy may become a dangerous procedure in spite of every precaution. This lesson cannot be too strongly impressed upon all those who see and treat patients with exophthalmic goitre. I want to emphasize therefore that iodine in any form should not be given to the patient with adenomatous or exophthalmic goitre, in the hope of permanently benefitting the patient. Such treatment rarely produces a real relief and is generally followed by exacerbation of symptoms. Furthermore, it deprives the patient of the striking benefits derived from the correct use of iodine before operation.

I may mention a modification of the usual method of administering iodine, which I have found to possess several advantages. I refer to the intravenous administration of iodine in the form of sodium iodide. I have found this method particularly applicable in patients with extreme emaciation and in those with gastro-intestinal symptoms such as vomiting and diarrhoea. Such patients tolerate iodine poorly whether given by mouth or per rectum. Sodium iodide, however, intravenously administered has been found to be very effective and most satisfactory. The method is also useful whenever a more rapid iodimization is desired than can be accomplished by the oral

administration of iodine, as in cases of acute hyperthyroid crisis. The intravenous use of sodium iodide is more prompt in its effect. A few days usually suffice to control the acute symptoms. Furthermore, the method is one of especial value in patients previously iodimized, who have had partial or complete relapse or even crisis, and in whom further administration of Lugol's solution by mouth is rather ineffective. In such cases a further beneficial effect can still be obtained by the intravenous use of sodium iodide. Finally we sometimes encounter occasional active exophthalmic goitre cases in which, even when iodine has not been previously given, the oral administration is only partially successful. The improvement in the patient's condition and the reduction in basal metabolism fall just short of the degree or level at which one would feel secure in performing a double resection. In this type of case two or three daily injections of ten grains of sodium iodide produce just enough further improvement in symptoms and metabolism to make the double operation entirely safe and free of anxiety for the surgeon. In the postoperative treatment, whenever glucose solutions of 5 per cent strength are given intravenously an ampule of ten grains of sodium iodide as prepared for example by Mulford & Co., can be conveniently administered by placing the drug directly into the glucose solution. No untoward effects have been observed when the drug was used to the extent of ten daily injections. The average period of five to seven days is usually sufficient to produce the desired effects. Instances of unusually prolonged intravenous administration of the drug showed a rather marked, hard swelling of the thyroid gland and an excessive accumulation of colloid, much as one finds after the prolonged oral administration of Lugol's solution.

As with many potent agents which have a decidedly beneficial therapeutic value when correctly used but which when incorrectly used may produce serious and even dangerous results, so it is with iodine, the incorrect use of which is today causing untold damage and great suffering to unsuspecting patients everywhere. The surgeon is in a favorable position to see the bad results of iodine therapy. The patient with a thyroid disorder who receives iodine indiscriminately frequently develops acute symptoms of hyperthyroidism and failing to obtain relief finally consults the surgeon with reference to operation. I may mention a few types of thyroid disorder which are frequently made worse by the incorrect use of iodine. The continued use of iodine in varying amounts in cases of colloid goitre without hyperthyroidism often converts this innocuous type into the active hyperplastic gland characteristic of Graves' disease. Many cases of exophthalmic goitre which we see at the present time owe their origin to the misuse of iodine in simple

colloid goitre Adenomatous goitres without hyperthyroidism or with only mild or moderate degrees of toxicity are commonly converted into those with symptoms of acute hyperthyroidism resulting occasionally even in crisis Leaving aside the small percentage of adenomatous goitres with hyperthyroidism in which we would suspect the presence of hyperplastic tissue comparable to Graves' disease and which would consequently respond favorably to intensive iodine treatment, we find that the majority of adenomatous goitres are activated by iodine It has been my general rule therefore to omit iodine in the majority of cases of adenoma In practically all of my cases of adenomatous goitre I have operated without the previous use of iodine and have never in a series of over six hundred cases had a death from postoperative hyperthyroidism or any other cause When one is able to operate in adenomatous cases with such a degree of safety, I prefer not to use iodine at all for the cases in which it might be useful are relatively few as compared to those in which increased toxicity is engendered by its use A considerable number of cases of adenoma have come to me in a condition of acute hyperthyroidism as a result of iodine therapy and have caused me considerable thought and anxiety as to when operation should be undertaken

I may mention an instance of a tragic result following the treatment of early Graves' disease with iodine in varying amounts over a period of several months A school teacher, aged 27, came to me first on June 9, 1924 She presented a typical early Graves' disease as indicated by classical moderate symptoms of hyperthyroidism such as loss of weight, nervousness, fatigability, tachycardia, tremor and emotionalism The von Graefe and Mobius eye signs were present The thyroid gland was moderately enlarged, had a granular feel and showed increased vascularity as indicated by thrills and bruits The pulse was 110 She had received general medical attention but as far as we could determine no iodine had been given The basal metabolic rate at the Life Extension Institute on June 5, 1924, was +48

I prescribed some suitable sedative treatment The matter of operation was discussed but the patient wished to have a period of medical treatment I then decided to try the effect of moderate doses of iodine over a short period She was accordingly given four minims of Lugol's solution twice a day together with sedatives for a period of a week and then three minims three times a day for a further period of three weeks One week after beginning this treatment the pulse had come down from 118 to 102, the symptoms had definitely improved and the patient had gained three pounds in weight I then discontinued the iodine and she was allowed to go on her summer vacation with simple instructions as to rest and diet

She returned for observation in November, 1924 The pulse was now 78 There were no thrills or bruits The gland however was still quite large and she had gained thirty-one pounds She had practically no complaints and seemed to be a medical cure I cautioned her against further iodine

She returned for observation again in February, 1925 The pulse was now 96 There were only mild symptoms of hyperthyroidism She complained of amenorrhoea and had lost three pounds in weight She consulted another physician in March, 1925 He immediately prescribed Lugol's solution in doses of three to five drops three times a day This was continued throughout March and April At the end of April, the patient developed what she called a "nervous breakdown" She was extremely nervous and excited and finally became unmanageable In view of the critical nervous manifestations, her physician prevailed upon the family to remove the patient to a hospital Under the impression doubtless that massive doses of iodine would control the severe hyperthyroidism, large doses of Lugol's solution were given three times a day while the patient was in the hospital I could not determine the exact amount but the patient stated that she practically drank iodine solution ad lib She said that she knew by the taste that the solution was given in great concentration and in very considerable amounts Probably as much as fifteen to twenty-five or thirty drops were given three times daily The patient continued to be unmanageable—she walked the floors at night, was very noisy and at times became so disturbing and even violent, that the superintendent of the institution insisted on her removal After consultation, the family was told that the patient was essentially mentally unbalanced and needed institutional care In a critically nervous condition she was removed to Bloomingdale Hospital on May 2, 1925 The iodine treatment was promptly discontinued Cold packs and other treatment calculated to control the great restlessness and excitement were instituted She remained in Bloomingdale Hospital all of May, June and July and was discharged on August 26th At the end of this time she had improved very definitely and had returned to practically the condition noted previously in February when I saw her before iodine had been used indiscriminately I saw the patient again in October, 1925 The pulse was 90 and there was a slight tremor However, general improvement was noted She weighed 158 pounds I saw her twice between October and December, 1925, placed her on simple sedative treatment and she continued to do well She consulted me recently again on April 19, 1927, at which time she was practically well Her pulse was 82, she had only very mild nervous symptoms and had resumed her work as a

teacher. She weighed 172 pounds. This to me was a most striking example of the acute exacerbation which may be produced in early Graves' disease by over-dosage of iodine.

In exophthalmic goitre several results may follow treatment with iodine. It has long been known that a rather small percentage of such cases will often do well after minute doses of iodine. This was known to the elder Kocher many years ago. However, the difficulty has always been of knowing which cases were suitable for this treatment. I have had a few successes in very early cases but have abandoned entirely the use of iodine excepting as a preoperative measure in the advanced cases on account of the uniformly bad results. The few successes following the use of iodine as a cure for exophthalmic goitre have probably done more harm than good for they have encouraged the present day orgy of indiscriminate dispensing of iodine by physicians, pharmacists and others in the mistaken notion that, given a goitre, iodine is always indicated. It is now a common occurrence to see results which are nothing short of calamitous following the abuse of iodine in exophthalmic goitre. Patients present themselves in a highly nervous, emotional and even irrational state frequently with a pulse rate of 180 to 200 or more. As a result, the best that can be done for these unfortunate victims is to condemn them to an indefinite period of acute suffering or to convert the acute iodine exacerbation into a somewhat less active phase by further iodine administration. Eventual cures cannot however be expected by the use of iodine even over periods of one to three years. At any time when the patient, for any cause, discontinues the iodine, the gland may again assume its former activity or become even more toxic than it had ever been before. Besides the disadvantages produced by the exacerbation of the disease iodine produces additional difficulties for the surgeon. The rapid accumulation of colloid in the gland causes it to become strikingly hard, fragile and firmly fixed about the trachea. At operation it is delivered with difficulty. The control of hemorrhage may be embarrassing since the gland substance will hardly hold a clamp or a suture.

Another error in the use of iodine is frequently seen. Most physicians appreciate that intensive iodine treatment will cause a marked fall in the metabolic rate and a striking improvement in the clinical picture of exophthalmic goitre. They therefore begin the administration of the drug with a view to subsequent operation. It happens however, that the period of maximum improvement following the administration of the iodine is wrongly timed. The operation is not undertaken within the average period of ten days following the inception of the treatment. When the patient ultimately presents herself to the

surgeon the quiescent and safe period has passed. Signs of renewed activity make their appearance and operation again becomes a matter of concern. The favorable period having been overlooked, a second intensive administration of iodine is not followed by the strikingly beneficial effects of the first course of iodine. Preliminary ligations may become advisable. I believe it is only fair to the surgeon to allow him to see the patient before the iodine is prescribed in order that he may better judge the operability as indicated by the degree of improvement and the fall in the metabolic rate. It should be emphasized that in the group of cases in which the quiescent period has been overlooked, in which relapse has occurred and finally in which further iodine administration had had an indifferent effect, the danger of postoperative hyperthyroidism is still lurking. In general, what has been said with reference to the indiscriminate use of iodine in exophthalmic goitre also holds in adenomatous goitre.

The administration of iodine to the pregnant mother with a view to preventing hypothyroidism in the child is a common practice today. Because of the demands made upon the thyroid gland in pregnancy it is doubtless rational to supply minimal doses of iodine to the mother who may have a colloid goitre. It not infrequently happens however that the differentiation is not made between a simple colloid and a hyperplastic gland. In fact, it is well known that the thyroid gland in the average healthy mother is, as a rule, more active during pregnancy. Consequently, when iodine is supplied to an already physiologically active gland the secretory function is increased. We have seen definite hyperthyroidism produced in this manner during pregnancy and continuing after delivery.

I have recently had an interesting experience in the administration of iodine to a young married woman seventeen years of age with a colloid goitre. She came to me first April 29, 1926, because of a simple thyroid enlargement without hyperthyroidism and because of the possible effects of this condition upon future pregnancy. Her physician had previously given her desiccated thyroid in amounts varying from one to three grains daily usually in alternating periods of two weeks followed by a week of no treatment. Simultaneously small doses of Lugol's solution were given in amounts varying from one to two and rarely three minims daily. This treatment extended over a period of six months, from April 29 to the middle of October, without appreciable effects as to symptoms or signs except that the patient seemed to improve and the circumference of the neck at the level of the thyroid isthmus had diminished from 35 to 32½ cm, a very satisfactory result. The patient then became pregnant. The treatment with thyroid extract and iodine in the doses mentioned

was continued and within a period of one month slight hyperthyroid symptoms developed and at the end of two months a very definite hyperthyroidism had developed. The pulse increased from 86 to 104. Mild thrills and moderate bruits made their appearance. The gland however continued to decrease slightly in size. The patient was nervous and tremulous. The condition was at once recognized and all therapy with thyroid extract and iodine was discontinued. At the next visit one month later the pulse was again 70, symptoms and signs of hyperthyroidism had again disappeared and her condition was as before. In the last three months thyroid extract was administered with periods of interruption in doses of gr I daily together with M I or M II of Lugol's solution with good results. I have reported this case in some detail to illustrate the fact that the thyroid during pregnancy is more sensitive to iodine and thyroid extract than at other times. Caution should therefore be exercised in the use of iodine or thyroid extract in pregnancy unless there is evidence of simple colloid enlargement without hyperplasia and without symptoms of hyperthyroidism. The matter of diagnosis becomes thus of extreme importance.

Finally, there seems to be almost a rage on the part of a great many physicians the world over, for prescribing iodine, often in enormous doses, to any and all kinds of goitre without regard to indications and type. The abuse of iodine has led to an unparalleled orgy of drug-vending by many ill-informed physicians, health centers and even the laity, not alone to goitrous patients but also to those suspected of having some form of goitre. Thus, I have seen simple cysts of the neck, lipomas, hygromas and even deep-seated tuberculous glands of the neck engulfed in the therapeutic iodine wave. In many instances, mild cases of hyperthyroidism have been acutely exacerbated and have become fulminating in their toxic manifestations. In others, the patients have been annoyed by an unnecessary iodism characterized by acne, itching, conjunctivitis and rhinitis.

In view of the striking and almost miraculous results of iodine when given under proper indications and in view of the equally appalling effects when it is administered indiscriminately and without correct indications, it behooves every physician who prescribes for goitrous patients, to thoroughly familiarize himself with the correct use of iodine. When Plummer's contribu-

tion is more generally understood and his directions more carefully followed the difficulties which I have briefly discussed will be avoided and the good results obtainable after both the medical and surgical treatment of goitre will be more universal. It behooves all of us, therefore, to spread this gospel among medical students and practitioners.

In concluding then let me briefly emphasize the following points. The administration of iodine causes hyperplastic thyroid tissue to revert to the simple colloid type of gland. Intensive iodine treatment, when given for the first time to the exophthalmic goitre patient causes a lull in the disease with marked amelioration of symptoms and signs, a fall in the metabolic rate and protects furthermore against dangerous post-operative hyperthyroidism. Further treatment with iodine has little or no effect upon patients with goitre who have received iodine over varying periods of time. Iodine causes a temporary remission of symptoms in exophthalmic goitre. Relapse and even crisis may follow in four to eight weeks following the discontinuance of iodine. Indiscriminate treatment with iodine increases the difficulties of the operative treatment and deprives the patient of the striking benefits derived from the correct use of iodine before operation. Intravenous administration of sodium iodide in doses of five to ten grains daily for five to ten days is more effective than Lugol's solution per mouth especially in patients with gastro-intestinal symptoms such as vomiting and diarrhoea. It is furthermore most useful in cases of acute hyperthyroid crisis and in patients previously indiscriminately iodized in whom the oral administration of iodine is only partially successful.

Indiscriminate use of iodine by the thyroid patient often results in the production of acute symptoms of hyperthyroidism. A simple colloid goitre may thus be converted into an active case of Graves' disease.

Adenomatous goitres without hyperthyroidism or with only mild degrees of toxicity are converted into those with symptoms of acute hyperthyroidism resulting occasionally even in crisis.

Iodine treatment in exophthalmic goitre should be reserved for the period before operation and should then be given intensively in doses of ten minims three times a day over a period of a week or ten days.

Great caution should be used in treating the pregnant woman with iodine.

## CORRECTION OF PHYSICAL DEFECTS IN SCHOOL CHILDREN\*

By DR FREDERICK W SEARS, SYRACUSE, N Y

THE rapidly increasing cost of public education makes it imperative from an economical as well as from a health standpoint that each individual child shall not be retarded in his educational progress by physical handicaps.

School medical examinations are absolutely necessary to discover these handicaps. The detection of physical defects is of practically no value unless through follow-up work these defects are in so far as possible corrected.

In cities and in some of the larger villages this work is progressing quite satisfactorily.

The conditions in the rural schools are in most instances deplorable. The rural school boards resent paying for school physical examinations for which they believe they get no returns.

School examiners become discouraged more from a lack of nursing assistance in securing corrections than from the inadequate pay they receive for these examinations.

To examine school children year after year and find that nothing has been done with the recommendations made the previous year does not stimulate the conscientious physician to do more thorough work nor does it stimulate the Board of Education to make better appropriations for this work. We have long felt that only by correcting these conditions and providing proper assistance from public health nurses for assisting in the physical examinations and especially in the follow-up work to secure corrections can we hope to secure better results.

Through competent nursing service provided by the Onondaga Health Association a plan was adopted by a rural health committee, appointed by that organization of which the writer was made chairman, for the purpose of making a demonstration as to the value of such assistance. The plan as worked out by the committee is as follows:

Upon request fifteen small one and two room schools which were considered to be in the greatest need of such work were selected by the five District School Superintendents of Onondaga County for the demonstration. Letters were sent to the school trustees of these schools, explaining our plan with the request that they give to the committee the names of the medical examiners who had been selected by them to examine these schools. The school examiners whose names were presented to us were told of the plan and asked if they would like such assistance and if so, to state the dates on which they wished to make the examinations in each particular school. Having obtained this information a public health nurse carrying with her the necessary equipment

visited the school selected on the day previous to the date set for the examination.

On that date the nurse tested the hearing and vision, weighed and measured and made out a history card for each child. She also screened off a portion of the room to be used for the examination.

On the day of the examination the nurse presented each child to the examiner with the clothing removed down to the waist line, assisted the doctor in making the examination and carefully recorded the results. Later the records of these examinations were carefully gone over by the nurse with the physician for the purpose of checking the corrections needed, the physician informing her as to the parents whom he believed would be able to pay for the corrections needed. Following this conference each family in which there were children with defects was visited by the nurse and arrangements made for the correction of defects by the family physician if the family was financially able to have it done and through the Red Cross for the indigent families. This work was begun in September, 1925, and the results more than met out expectations.

There were enrolled in these fifteen schools 464 pupils, 432 of whom were examined. It was found that 84 per cent showed defects that should be corrected, many of them having more than one defect, the total defects being 763.

Within the first year 26 per cent of vision defects were corrected, and 55 per cent of defected teeth corrections made. Many diseased tonsils were removed and home and school conditions were improved. Toxin-antitoxin was given to nearly all of the school and pre-school children in most of these school districts.

During the past year five additional schools were examined under the same plan. The enrollment in these five schools was 485 and the number examined was 440. Defects 321. The work of correcting defects has been continued in the original fifteen schools and is being carried on in the five additional schools. In five of the original schools practically one hundred per cent defective teeth have been corrected. This includes 202 dental corrections and the removal of diseased tonsils in twenty-five additional children this year.

As a result of this demonstration the medical examiners of these schools have been encouraged to do more thorough work and we have been unable to meet the requests of all of the health officers of the county to have this work extended to their districts. The school trustees of these various districts have expressed themselves as well satisfied with the work done.

In February of this year a request for the

\*Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 11, 1927.

appointment of four additional public health nurses by the Board of Supervisors of Onondaga County was so vigorously presented by all of the twenty-seven health officers of the County, by public spirited citizens and by the parents whose children had been benefitted, that the request was granted. The work is about to be formulated and it is expected that within the

very near future Onondaga County will be divided into five nursing districts, each such district will have assigned to it a public health nurse who will reside in the district and will do generalized public health nursing not only for the school child, but through pre-natal and pre-school efforts to prevention of defects among school children

### PATHOLOGY OF URTICARIA PIGMENTOSA\*

By J FRANK FRASER, M D and MAURICE N RICHTER, M D, NEW YORK, N Y

**M**ICROSCOPIC examination of the lesions of Urticaria pigmentosa was made in eleven cases, seven of which were of the so-called "adult type"

The pathologic alterations in the tissues of both infantile and adult cases were the same, and consist of

- 1 Pathologic mast cell accumulation in the corium
- 2 Rarefaction of the collagen bundles with fraying and rupture of the elastin
- 3 Increase in the amount of pigment (melanin) in the epidermis, and its presence in deeper areas

An excess of mast cells was found in all our cases, though repeated examinations were sometimes necessary to establish this. The mast cells were chiefly about the base of the papillæ and surrounding the blood capillaries. The excess of mast cells is not, however, pathognomonic of the disease. In arsenical keratosis, for example, we have observed a

cellular accumulation in which mast cells were as numerous as in some cases of Urticaria pigmentosa

We have not found an excess of mast cells in the intervening healthy skin, nor do we find their number to be increased by irritation of the lesions

The mast cells in the lesions of Urticaria pigmentosa are identical with those normally present in various connective tissues, but are morphologically and genetically different from the mast cells (basophilic Leucocytes) of the blood. They are not emigrated blood cells, but are formed in situ by the development of metachromatic granules in the cytoplasm of certain connective tissue cells

The pigment in the lesion is melanin. The distribution of the pigment was investigated for us in two cases by Dr Gilbert Dalldorf who found it present in both epidermis and corium

The melanin in the deeper areas is in perivascular connective tissue cells. This situation brings it in close relationship with the mast cells which are also perivascular, but it is possible to determine that the pigment is not in the mast cells

\* Abstract of a paper read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 11, 1927, to be published in the Archives of Dermatology and Syphilis.

## CONFERENCE OF SECRETARIES OF COUNTY MEDICAL SOCIETIES

The Secretaries of the County Medical Societies of the State of New York met on September 15th in Albany in a five-hour session of their second annual conference, which is reported on page 1094 of this Journal. The problems that were discussed were those which must be settled by the medical profession collectively as distinguished from the individual members of that profession. The subject of Graduate Education, for example, was presented from the standpoint of the society, which makes the arrangements for a course

Attendance at the lectures and study of the topics are the functions of the individual physicians

An individual doctor treats each workman as an individual case, but the representatives of the Medical Society assist the lawmakers and State Commissions to formulate policies and standards regarding liabilities and compensation connected with the injury

The conference is an argument to every doctor that he shall join his county society, and take an active interest in its activities

appointment of four additional public health nurses by the Board of Supervisors of Onondaga County was so vigorously presented by all of the twenty-seven health officers of the County, by public spirited citizens and by the parents whose children had been benefitted, that the request was granted. The work is about to be formulated and it is expected that within the

very near future Onondaga County will be divided into five nursing districts, each such district will have assigned to it a public health nurse who will reside in the district and will do generalized public health nursing not only for the school child, but through pre-natal and pre-school efforts to prevention of defects among school children

## PATHOLOGY OF URTICARIA PIGMENTOSA\*

By J FRANK FRASER, M D and MAURICE N RICHTER, M D, NEW YORK, N Y

**M**ICROSCOPIC examination of the lesions of Urticaria pigmentosa was made in eleven cases, seven of which were of the so-called "adult type"

The pathologic alterations in the tissues of both infantile and adult cases were the same, and consist of

- 1 Pathologic mast cell accumulation in the corium
- 2 Rarefaction of the collagen bundles with fraying and rupture of the elastin
- 3 Increase in the amount of pigment (melanin) in the epidermis, and its presence in deeper areas

An excess of mast cells was found in all our cases, though repeated examinations were sometimes necessary to establish this. The mast cells were chiefly about the base of the papillae and surrounding the blood capillaries. The excess of mast cells is not, however, pathognomonic of the disease. In arsenical keratosis, for example, we have observed a

cellular accumulation in which mast cells were as numerous as in some cases of Urticaria pigmentosa

We have not found an excess of mast cells in the intervening healthy skin, nor do we find their number to be increased by irritation of the lesions

The mast cells in the lesions of Urticaria pigmentosa are identical with those normally present in various connective tissues, but are morphologically and genetically different from the mast cells (basophilic Leucocytes) of the blood. They are not emigrated blood cells, but are formed in situ by the development of metachromatic granules in the cytoplasm of certain connective tissue cells

The pigment in the lesion is melanin. The distribution of the pigment was investigated for us in two cases by Dr Gilbert Dalldorf who found it present in both epidermis and corium

The melanin in the deeper areas is in perivascular connective tissue cells. This situation brings it in close relationship with the mast cells which are also perivascular, but it is possible to determine that the pigment is not in the mast cells

\* Abstract of a paper read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls N Y, May 11, 1927, to be published in the Archives of Dermatology and Syphilis

What	How long
Interval between first symptoms and treatment	
X-ray	Radium
Housing	Economic status
No of physicians consulted	
No of irregular practitioners consulted

Address	
Telephone number	

During the first seven months after the committees began work, 30 cases of cancer were reported, but during the same period 29 cancer cases died, of whom only 5 had been reported. The letter continues

"It is realized that the response of the Newton physicians has not been as complete as might be desired, but the present indications point to an improvement in this respect. As Newton is the first city in the United States to report its cancer cases, this statement seems advisable as it indicates a method which might be used in other selected communities to add materially to our knowledge of this pressing problem. Also appreciation should be expressed of the fact that busy practitioners of a community are willing to take on this added obligation."

A report such as this is of very great value, not merely for the statistics that are developed, but because it indicates a practical way by which physicians may give direct aid to the solution of the cancer problem.

---

## LOOKING BACKWARD

### THE JOURNAL TWENTY-FIVE YEARS AGO

*Infant Feeding* — The simplicity of infant feeding today is in great contrast with the complicated formulae of a quarter century ago. This Journal for October 1902 says editorially:

"The importance of exactness in all stages of experimenting in the preparation of infant food by modifying milk was insisted upon. This was a frequent cause for disagreement. One physician may believe in giving starch in the early weeks of life, while another may not. No proper deduction can be arrived at unless we know exactly how much starch each experimenter is giving and how much of the other elements of the food, only in this way can it be determined whether those who are in favor of giving starch are in the right or not."

"If human milk cannot be obtained, the most perfect substitute for it is cow's milk, which should be scientifically modified to correspond as closely as possible not only with human milk in general, but with the human milk that is consumed by each individual child. A careful study of human breast milk demonstrates that it is a varying compound with the three essentials of food—namely, fat, sugar and proteids, that the percentages of these elements are far from constant, not only in different individuals, but also in the same individual under varying circumstances. Human breast milk, then, is a varying food. This fact should be noted and due weight be given it in preparing a substitute food so that the greatest variety of percentages

of the different elements of the milk may be obtained, as well as a great variety of combinations of them, according to the judgment of the physician. The percentages and the ingredients should be determined not by any given standard of the average in mother's milk, but by the study of the needs of the individual infant. From this principle has arisen the system of milk laboratories, where the needs of individual patients can be met with exactness, and the different elements of the food may be prescribed with the same precision as a prescription for medicine. This, Dr. Rotch claims, has been accomplished in America by the Walker-Gordon system of laboratories. Not only are ingredients of importance, but percentages of these ingredients are essential to the construction of the best food."

"The cream of the Holstein breed is a much finer emulsion than that of the Jersey cow, moreover, when broken down the emulsion is much more easily restored—that is, it emulsifies better and resists a destruction of its elements, such as occurs when cream is produced—than the cream of the Jerseys and the Guernseys."

All this is in contrast to the modern conception that babies are not merely delicate chemical laboratories to be run by the doctor and nurse but living mechanisms with wide powers to adapt their own chemical reactions to the needs of their bodies.

## AMBULANCE CHASING

There are about 45,000 serious accidents in New York City every year, and the settlement of the resulting claims costs many millions of dollars. Lawyers have the profitable custom of taking one half of the awards for their alleged services in settling the claims of the victims, and the possibilities of graft are very great, especially since insurance companies often prefer to settle with the claimants rather than stand the cost of fighting them. After all, the insurance companies lose little or nothing, for they base their premiums on their losses, and if they make extra large profits because of lower claims, they have to reduce their rates, and so their profits tend to remain constant no matter how many or few the claims may be.

Almost any accident is good for a few hun-

dred dollars graft, and the system of securing clients is well organized among lawyers of a certain class. It even extends to actually following the ambulances which go out from the city hospitals, to policemen who report accidents, and even to a few physicians who sell their services to the chasers.

The Brooklyn Daily Eagle is printing a daily column of exposure of ambulance chasing, and shows that the courts of the city are overburdened with cases brought by a very few lawyers. It suggests that the lawyers apply their code of ethics and purge the profession of those who fatten themselves by organized solicitation of cases.

The condition of affairs is of interest to physicians, for the testimony of a doctor is needed in every suit for damages to the body.

## DR H EDWIN LEWIS

Medical editorship lost a conspicuous leader on August 6, 1927, in the death of Dr H Edwin Lewis, Editor of *American Medicine* since 1908. Dr Lewis was a born literary man and editor, whose talents were inherited from his mother and fostered by his wife. He founded the *Vermont Medical Monthly* in 1907 while he was a medical student in the University of Vermont. He edited the *International Journal of Surgery* while practicing his specialty of tuberculosis in New York City, and in

this editorship he was succeeded by his brother, Dr Frank C Lewis.

Dr Lewis was a hard worker, original and independent, enthusiastic and optimistic, and anxious that the weaker man should have his fair chance even at some sacrifice from the stronger. He represented that best type of medical editor who was anxious to obtain news of every advance in medicine and to impart it to his brother practitioners as soon as he knew it himself.

## CANCER MORBIDITY

What is the number of cancer cases per thousand of population?

This question is discussed on page 809 of the September 3rd issue of the *Journal of the American Medical Association*. The article consists of a letter signed by Dr F G Curtis of Newton, Massachusetts, and Dr G H Bigelow of Boston, outlining the efforts of the physicians of Newton to secure a list of cancer cases in the city.

The letter first discussed the plan that the State Department of Health should make cancer a reportable disease, but it rejected the plan on the ground that cancer, unlike such a disease as measles, has no distinguishing mark, especially in its early stages. But the members of the Newton Medical Club voted to report their cancer cases voluntarily, and the Club appointed committees to direct the work and to establish a cancer clinic in the Newton Hospital. The following report form was adopted:

### CANCER MORBIDITY REPORT FORM

Name	Sex	Age
Address		
Civil condition		
Type of disease		
Location of disease		
Date of first symptom		
Character of first symptom	Pain, Lump, Abnormal	
discharge		
Date of first consulting physician		
Has any member of patient's family had cancer		
Relationship		
Has patient ever been in close association with a cancer patient		
Injury in site of cancer		
Operation for cancer—what		
Operation other than for cancer—what		
Does patient use alcohol		
Does patient smoke (pipe, cigar, cigarette)—chew		
Does patient have periodic craving for unusual articles of food		
What		
Does patient eat little or much salt		
What foods does patient never eat		
Is patient constipated		
Has patient suffered from chronic disease		

What	How long
Interval between first symptoms and treatment	
X-ray	Radium
Housing	Economic status
No of physicians consulted	
No of irregular practitioners consulted	
Possible precancerous condition at site of disease	Mole,
wart leukoplakia, ulcer, uterine tear, chronic irrita-	tion from teeth, from corsets, other known chronic
irritation.

**Prevention of Rheumatic Heart Disease in Children**—After quoting statistics showing the prevalence of rheumatism and heart disease in early childhood, J F Halls Dally deplores the lack of consideration that has been given to the preventive aspect of rheumatic heart disease in children. In general, statements are made to the effect that in onset rheumatism in childhood is insidious, in aspect protean, and that the appearance of very slight symptoms, such, for example, as sore throat or stiffness of the muscles, should put one on guard against the possible development of definite stigmata of rheumatism. Yet at the very time that a child complains of "growing pains" or of sore throat, that child may already be the victim of rheumatism, and acute and unmistakable symptoms may rapidly supervene. The early recognition of rheumatism in children is exceedingly difficult. That so little has been done in the way of prevention is not to be wondered at when one considers our lack of knowledge as to the exact etiology of rheumatism. The author urges that a broader view of the etiology be taken—that while the incidence of streptococcal infection in certain instances cannot be denied, it is more in accord with our present imperfect understanding to assume that such infection is incidental rather than causative, and, similarly to tuberculosis, occurs only when some special character of soil, *i.e.* the rheumatic diathesis, promotes its evolution. As our appreciation of the causal factor or factors of the "rheumatic" diathesis is slight, in order to grapple effectively with the problem it is essential that the life histories of potentially disposed children should be carefully studied over long periods, side by side with those of actually rheumatic children, contrasting with these groups children who are debilitated from other causes, and at the same time taking healthy children of equivalent ages as controls. A beginning has been made along these lines by the establishment in 1926 of a "Children's Cardiac Clinic" at the St Marylebone General Dispensary. To this clinic children are brought for examination whenever possible prior to the manifestation of rheumatic symptoms, and for treatment where the disease already exists. An effort is made by timely advice and appropriate therapy to raise the *vis resistentia* of the three chief tissues vulnerable to attack, namely, the muscles—including the heart—the skin and the mucous membranes, of the child against adverse climatic and other influences. In this way it is believed that weakly children of rheumatic stock may be aided to work out their own immunity.—*The British Journal of Children's Diseases*, April-June, 1927.

**Symptomatology of Acrodynia as Indicating an Allergic Origin**—Arthur C Helmick (*Archives of Pediatrics*, July, 1927, xlv, 7) traces a close analogy between the symptoms of

acrodynia and those of allergy, and urges that in investigating the etiology of the disease the possibility of its being a form of allergy be taken into consideration. The constant symptoms in acrodynia are the nervous symptoms, the skin changes, and the alteration in the hands and feet. If one holds in mind the six most common allergic phenomena, namely, cyclic vomiting, urticaria, eczema, rhinitis, asthma, and angioneurotic edema, one can mould such a striking resemblance to acrodynia that it does not seem possible to question their relationship. With reference to the nervous symptoms, the sudden onset, profound discomfort, constant rubbing and scratching when any part of the surface of the body is exposed, are common to both conditions, and suggest that the general effect is not that produced by an illness, but rather that coming from external sources, such as might result from constant skin irritation. Practically every evidence of skin disturbance in acrodynia is paralleled in eczema or urticaria, and regardless of the severity of the skin lesion in either instance, there are always points of similarity. The symptoms referable to the hands and feet typify an allergic reaction to such a degree that any other conclusion as to their origin would scarcely be considered. The nose and throat symptoms of acrodynia have their exact prototype in rhinitis and hay fever. The mouth condition is the natural result of obstructed nasal passages, whereby the oral cavity becomes a welcome host to pathogenic microorganisms. By some, important significance has been attached to enlarged lymph glands, and suspicion has been aroused of their harboring infection. If the disease were due to infected lymph glands these would always be enlarged, but this is not true in acrodynia. In the author's series, the degree of glandular involvement depended upon the severity of the skin invasion. Symptoms referable to the chest and abdomen also parallel those caused by allergy. The irregular laboratory reports in cases of acrodynia are very much the same as those noted in allergy, and evidence the possibility of disturbed metabolism. In neither acrodynia nor allergy has there been a constant reaction to any type of therapy. In determining the correctness of this hypothesis as to the etiology of acrodynia, the author urges the importance of studying hereditary tendencies, blood chemistry, especially as to calcium content, and the reaction of the individual to calcium and adrenalin.

**Abdominal Stitch in the Side**—H Herxheimer discusses in the *Deutsche medizinische Wochenschrift*, July 1, 1927, this very common symptom, concerning the nature of which so little is known. It is believed by some old and recent writers to proceed from the spleen. The author refers to the familiar pain in the side

# MEDICAL PROGRESS

**Some Medical and Psychological Aspects of Tattooing**—Writing in the *British Journal of Dermatology and Syphilis*, July, 1927, xxxix, 7, Morris J. Cohen states that tattooing is probably as old as the human race. In many respects it is a primitive stage of and substitute for clothing. Perhaps it is a display of the decorative instinct, and unquestionably it is often employed as a sex lure. The psychological make-up of the tattooed is frequently apparent from the subjects displayed by the indelible marks. Some tattoo marks give evidence of Freud's *Œdipus complex*. There is some evidence that among the tattooed venereal diseases are rife than among the non-tattooed. A nonsensical notion exists among some classes of the laity that tattooing is a protection against venereal disease, and also that it replaces vaccination. Not long ago a rumor spread through a portion of the Indian army and elsewhere that medical men preferred tattooing to vaccination. This outrageous falsehood was immediately refuted. Tattooing may become a dangerous process. Syphilis, tuberculosis, erysipelas, septicaemia, abscess, etc., have been contracted in this way. Ernest Mallan has recently recorded a case of epithelial papilloma of doubtful malignancy originating in a tattoo mark in which the pigment was regarded as the causal agent. Eczema may follow, and persist only in tattooed areas, and in several instances coming under the author's observation the design was obliterated through sepsis. Frequently attempts have been made to remove the marks. In ancient Roman days cantharides was used to eradicate the pigment. Nowadays the most efficacious methods are excision of the pigmented areas, harpooning of the pigment granules, and the use of the galvano-cautery under local anesthesia. Another method, that of Variot, consists in rubbing in lunar caustic and tannin. This leads to inflammation, and thereafter a necrotic scab is thrown off. This process takes a great deal of time and is painful. According to Buchanan, applications of strong acetic acid, potash, hydrochloric acid, and glycerole of papain have been employed for the removal of tattoo marks.

**Passive Immunization Against Tetanus by the Cutaneous Route**—A. Besredka and S. Nakagawa conclude from the results of a series of experiments on guinea pigs that antitetanic serum, when applied to the shaved skin 24 hours before the toxin, preserves the animals from tetanus. If applied from 1 to 3 hours after the toxin this antitetanic dressing protects from fatal tetanus although the animals develop transitory tetanic troubles. When applied in liquid form

as a dressing the serum acts especially on the tetanic toxin present in the area of the dressing. In other words it exerts a local action. Applied in the form of a cream it may act further on the toxin injected at a distance. In no case did any anaphylactic action develop from this application of the serum. Thus the principle which had been found efficacious against virulent infectious cocci has been found to apply equally to the bacteria which produce only a toxin. The antiviral virus of pyogenic cocci, however, has been used successfully as a local application to actual lesions and whether or not this new use of tetanus antitoxin will neutralize the toxin in actual clinical wounds in mankind does not come up for consideration, for the experimenters dealt only with laboratory tetanus. Antitoxin has often been applied locally to wounds but apparently only in conjunction with the injection treatment.—*Annales de l'Institut Pasteur*, June, 1927.

**Tetanus Following Parasitism of the Sand Flea (Jigger)**—Dr. W. Rohardt of Rio Grande, Brazil, has seen four cases in which tetanus developed in ulcers of the feet due to infestation with the sand flea. At first sight the fact that tetanus infection occurred in ulcers of the soles in subjects who habitually walk barefoot in soil which reeks with horse manure, garden earth, etc., would not seem remarkable, but this source of tetanus does not seem to be an ordinary one and the author saw his four patients within the space of six weeks which gives the disease a sort of epidemic quality. The female sand flea deposits its ova beneath the skin and these give rise to maggots which penetrate and cause various types of lesion—"boils," burrows, fistulae, and open sores. Lesions are common on the soles and between the toes and the author has seen particularly dirty individuals with hundreds of boil-like lesions on the surface. The infestation commonly passes as something quite harmless. Clinically the cases were a surprise for the tetanus antitoxin, given early and in all forms, proved a total failure in the first two patients treated—a boy of 6 and a woman of 50. Death took place on the third hospital day. When the other patients were admitted the author feared to trust the serum at all and placed both on large doses of chloral which kept down the seizures and allowed the patients to recover. The first of the recovered cases occurred in a strong boy of 14 who was discharged inside of 3 weeks, while the second patient, a consumptive epileptic, was under treatment 5 weeks.—*Münchener medizinische Wochenschrift*, June 24, 1927.

urologic clinic of Professor Rochet a tight urethral stricture was discovered. The urethra was dilated and the patient began to improve. Three years later he was in relative health, with blood pressure down to nearly normal. A little pus remained in the urine with slight nitrogen retention. The authors appear to believe that an ascending nephritis had been added to a previous chronic nephritis although the marked improvement following dilatation suggested that the entire process dated from the stricture. The second case ended fatally and autopsy revealed an old interstitial nephritis with an exacerbation due to urethral stricture and ascending infection. Dilatation had been interrupted by a fatal pneumonia. The third case resembled the preceding, but the patient's life was cut short by cancer of the stomach. The thesis of the authors seems to be that even the long standing "medical" nephritis of these patients might have been due originally to the presence of the ancient strictures, although the mechanism would necessarily have been different from the superadded ascending nephritis of later years.—*Journal de médecine de Lyon*, June 5, 1927

**Swine Plague in Man**—Dr Schmitter of Offenbach describes a recent epidemic occurring in his city, a paratyphus-like malady attributed to infected ice. At first there seemed to be no doubt of the correct diagnosis of paratyphus as based on the finds in the blood, stools, and urine and in the suspected ice, but the epidemiology differed from that of paratyphus in some respects and Professor Braun of the Hygienic Institute, Frankfurt, was able to show that the offending organism was not that of paratyphus but the closely related organism of swine plague, which stands nearest to paratyphus B. Doubtless in the past swine plague has often masked infections of the paratyphus group. Clinically as well as bacteriologically the analogy between the two affections is striking, but as already pointed out the epidemiology must be taken into account. In this episode 150 individuals had partaken of ice, which was artificial and not prepared under hygienic inspection. Victims and suspects were promptly isolated and the ice condemned, but while the epidemic was soon checked not much light was thrown on the problem of ice infection. The most probable view is that the ice manufacturer's wife was a carrier. She did not develop the disease herself but her stools were found to contain the bacillus, although for a few days only. Before taking up the ice business the couple had farmed and the woman had tended the pigs. The domestic arrangements of the couple were crude and presumably insanitary and there were various ways in which the ice could

have become infected after the water had been boiled on the hearth fire—during cooling and after coming out of the machine. Two days' supply was made at a time. The woman took the ice cakes from the machine with a common ladle and gave them out to consumers. Bacteriological examination of apparatus was negative.—*Muenchener medizinische Wochenschrift*, June 17, 1927

**The Cause and Prevention of the Increasingly High Mortality in the Acute Surgical Abdomen**—John O. Bower quotes statistics showing that in England and Wales from the years 1913 to 1923 the mortality from appendicitis increased 73 per cent, and in the United States it increased 223 per cent. During the past ten years the increase of the death rate from appendicitis was 9 per cent greater than that from cancer. In an analysis of 1,010 cases of acute surgical abdomen, Bowers found that the abnormally high mortality rate was due for the most part to the loss of time between onset of symptoms and operation. This can be prevented by the education of the public through the family physician. The conditions included in this series of 1,010 cases, in the order of their importance, were appendicitis, intestinal obstruction, acute perforation of the duodenum or stomach, acute pancreatitis, ectopic pregnancy, and acute perforation of the gall-bladder. In ectopic pregnancy nature will, in the majority of cases, take care of the bleeding. An individual suffering from a perforated gall-bladder, duodenum, or stomach, or from acute pancreatitis, will demand relief. It is, therefore, acute appendicitis and intestinal obstruction that require consideration, because of (1) the insidiousness of the onset, (2) the patient's delay in calling a physician, (3) the frequency with which laxatives have been administered, and (4) the delay due to the physician's temporizing with the patient and the family. As a rule, severe abdominal pain in patients who have been previously well, and which lasts as long as six hours, is caused by conditions needing surgical intervention. The reduction of time between the onset of symptoms and operation can be successfully brought about by obtaining the cooperation of the staff and physicians who refer patients to the hospital. This has been done at the Samaritan Hospital, Philadelphia, by sending a letter emphasizing the importance of diminishing the time between the onset of symptoms and operation, of education relative to the use of laxatives in the presence of abdominal pain, and of recognizing the fact that the time element affects the prognosis. Gangrene may occur as early as five hours and perforation as early as twelve.—*American Journal of the Medical Sciences*, August, 1927

after intense exertion, but it has been shown in such cases that the spleen is not swollen but considerably contracted. The author examined 42 older children and adolescents in regard to this symptom, obtaining answers to his questions, and in addition made a careful physical examination. He sums up what is known as follows: stitch in the side is most common in persons between 10 and 20 years of age and follows only on certain kinds of exertion in which there is a steady rhythm, such as walking and running. It subsides spontaneously when the exertion ceases. It is most apt to supervene after a meal and there is no association between the violence of the exertion and severity of the pain. The seat is always abdominal and hence it is quite unrelated to sensations in the thoracic wall. It is not a phenomenon of exhaustion for it may supervene early, before the exercise has become vigorous. Neither the spleen nor the liver is concerned in its production. The frequent supervision with filled stomach makes it likely that the suspensory ligaments and folds of the stomach and intestine play a rôle. It has sometimes been possible to relieve the stitch by strongly compressing the abdomen. We do not, of course, know the exact mechanism, but the writer believes it is somehow connected with the rhythm of running, etc., which is transmitted to the supporting folds of the stomach when the latter is filled.

**Insulin in the Treatment of Pregnancy Toxemia**—Professor E. Vogt of the Tübingen University Gynecological Clinic sums up the results of an exhaustive theoretic and practical study of this subject as follows: Pure insulin therapy has only a symptomatic value in this group of affections but when glucose is added the combination therapy is of a distinctly causal nature. This treatment can be carried out only in hospital practice and under the most rigid control, checked up by urine and blood examinations. In the mild type of hyperemesis the simple insulin treatment may suffice, but in all others glucose must be given intravenously with reference to the general condition, weight, and degree of acidosis. In no case in which interruption of pregnancy seems indicated should we fail to use the insulin-glucose treatment first. In eclampsia the treatment must be strongly individualized, and in the more severe cases it is best to speed up delivery and if the convulsions persist to give the combined treatment. Dosage must be strictly individualized on a basis of blood and urine finds, weight, etc. In the medium and mild cases of eclampsia it is possible to use conservatism and expectancy and any of the plans in use may be sufficient. Whether the combined treatment has any advantages over the older methods must be decided later. This should be superior to the narcotic method of treatment because of its causal character.—*Klinsche Wochenschrift*, July 9, 1927.

**"Polycythemia Hypertonica"**—F. Parkes Weber, writing in the *British Medical Journal*, July 16, 1927, II, 3471, calls attention to the fact that in typical cases of splenomegalic polycythemia (Vasquez-Osler disease), in spite of the extremely high so-called "blood viscosity" (due to the great excess of erythrocytes in the blood) the blood pressure is only slightly if at all above the normal, and the heart is scarcely if at all hypertrophied. The so-called "polycythemia hypertonica" without splenomegaly, to which F. Gaisbock drew special attention in 1904 and 1905, seems probably to be a secondary or symptomatic polycythemia, connected in some way with the persistent high blood pressure of early stages of granular kidney, or with primary arterial hypertension without definite signs of renal disease. The syndrome is not rare, occurs chiefly in middle-aged persons, probably more frequently in males, and perhaps Hebrews are more often affected than others. From true splenomegalic polycythemia it is distinguished by the absence of splenomegaly, by the higher blood pressure, and the absence of marked facial cyanosis. The syndrome may represent merely a phase in the course of a case of high blood pressure, the polycythemia disappearing after a time, though the high blood pressure persists or increases. Weber describes an illustrative case in which, in 1920, the erythrocyte count was 8,000,000, the hemoglobin 130 per cent, and the systolic blood pressure 180 to 210 mm Hg. In 1927, the systolic blood pressure was 205 mm Hg, and the diastolic 150 mm, the blood count showed erythrocytes 5,100,000 and hemoglobin 90 per cent. The urine examination indicated an early stage of granular kidney. In spite of business and other worries, this patient's general condition has, on the whole, remained remarkably good. This suggests the question of polycythemia being a somewhat favorable sign in cases of persistent high blood pressure and early granular kidney. Weber thinks it must be taken as of relatively favorable prognostic significance, inasmuch as polycythemia, as Del Baere points out, to some extent relieves the heart from overwork (the increased number of red cells carrying a greater supply of oxygen to the tissues) and thus delays the effects of persistent high blood pressure.

**Latent Stricture of the Urethra as a Cause of "Medical" Nephritis**—L. Bouchut and P. P. Ravault publish three cases of this nature, in stating that this association of cause and effect is commonly overlooked, referring of course to medical nephritis only and not to the surgical form of pyelonephritis from back pressure. The first patient apparently suffered from subacute medical nephritis with albuminuria, edema, and high blood pressure. There were no disorders of micturition. On this background an acute exacerbation developed with hematuria and at the

as a physician or surgeon, in the city of New York, before he shall have been examined in physic or surgery, and approved of and admitted by one of his majesty's council, the judges of the supreme court, the king's attorney general, and the mayor of the city of New York, for the time being, or by any three or more of them, taking to their assistance for such examinations such proper person or persons as they in their discretion shall think fit" The penalty under this statute for practicing medicine without a license was the forfeiture of the sum of "five pounds" for every such offense

From the earliest times statutory efforts were being made for the protection of the public health. Infectious and contagious diseases or "infectious distempers" as they were then called, was a subject frequently before the legislature. In 1784 an act was passed to prevent the bringing of "infectious distempers into New York City," and by this law Bedloe's Island was made a quarantine station. At that time yellow fever was the most feared of the contagious diseases, and special precautions were maintained in regard to ships from southern ports which landed in our waters during the warm season.

New York City was a pioneer in quarantine regulation. It was not until 1796 that regulations of this kind were extended to other cities, when quarantine was established at Hudson and at Albany. By this law a physician was appointed to inspect vessels that entered the harbor, and for this inspection he was allowed a fee of twenty-eight shillings or about seven dollars, but carrying at that time a purchase value of probably about twenty-five dollars in our money. It was at this period that through an act of the legislature Governor's Island was set aside for quarantine purposes, and temporary buildings and tents were erected to care for infectious cases.

1792 saw the enactment of a law governing the practice of medicine in the City and County of New York. This law required that before being licensed to practice a student of medicine should study with some authorized practitioner for two years if he were a college graduate, and for one year longer if he had not had the benefit of a college education. After this study, he was required to be examined by three medical practitioners other than those with whom he had studied, and this examination was carried on in the presence of the Governor and certain other public officers. For practicing medicine without a license, a fine of seven pounds sterling was imposed, and it was further provided that an unlicensed practitioner could not maintain an action to recover compensation for his services.

Five years later a more stringent act to

"regulate the practice of physic and surgery in this state" was carried through. An examination of the records reveals that New York State was from the very beginning a pioneer in medical legislation. The impetus which gave rise to these early statutes was the contemporaneous recognition of the low estate to which the medical profession had fallen, due to the fact that in the new and unsettled regions quackery had flourished without restraint.

"Few physicians among us are eminent for their skill," wrote William Smith, the colonial historian of New York, in 1758. "Quacks abound like locusts in Egypt, and too many have recommended themselves to a full practice and profitable subsistence. This is the less to be wondered at, as the profession is under no kind of regulation. Loud as the call is, to our shame be it remembered, we have no law to protect the lives of the king's subjects from the mal-practice of pretenders. Any man, at his pleasure, sets up for physician, apothecary and chirurgeon. No candidates are either examined or licensed, or were sworn to fair practice."

There were no chiropractors in 1767, but apparently there were those from whom the chiropractors and other modern day cultists may trace their lineal descent. At that time (nine years before the Revolution), Dr. Middleton wrote:

"Yet, many, too many, are the instances, even in this place, of men, otherwise valuable for their penetration and good sense, who have given up their own judgments to the opinions of the credulous vulgar, and joining in the belief of nostrums, or secret cures, have countenanced and even employed the most obscure and superficial traders in physic. While the practitioner of modesty and real merit, conscious of his own integrity and knowledge and scorning the little arts of such licensed freebooters and secret homicides or to stoop to the unreasonable humors or petulance of every simple employer, has often had very circumscribed practice, or has been abandoned in favor of some ignorant or mercenary sycophant. This conduct in such men will ever discourage genuine worth and the prospect of farther discoveries in that useful profession, which in all time, and among all polite nations, has ever been esteemed honorable, and worthy of men of the first rank and learning."

"Such being the state of physic here, what wonder is that this city should be pestered in so remarkable a manner with the needy outcasts of other places, in the characters of doctors, or that this profession of all others, should be the receptacle and resource for the refuse of every other trade and employment? The wonder indeed is that we should be such

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## A BRIEF EXCURSION INTO EARLY MEDICAL LEGISLATION

There is a study of amazing interest in the early laws governing the practice of medicine. The problems with which we all are so familiar apparently are not new. Many of the difficulties which we are now called upon to combat are almost as old as the white settlement upon Manhattan Island. The struggle of the medical profession to protect the dignity of its calling and to safeguard the public against charlatanism, dates back more than 250 years.

The earliest record of any act regulating the practice of medicine is found in the old Dutch annals. On the 2nd of February, 1652, the old Dutch archives instruct us that "On the petition of the chirurgens of New Amsterdam, that none but they alone be allowed to shave, the director and council understand that shaving doth not appertain exclusively to chirurgery, but is an appendix thereunto, that no man can be prevented operating on himself, nor to do another the friendly act, provided it be through courtesy, and not for gain, which is hereby forbidden. It was then further ordered that ship-barbers shall not be allowed to dress any wounds nor minister any potions on shore, without the previous knowledge and special consent of the petitioners, or at least of Dr La Montague."

Legislative attempts to interfere with or undermine the sacred confidential relationship existing between patient and physician, then as now met with the opposition of the medical profession. In December, 1657, a city ordinance was passed by the schout, burgo-master and schepens giving notice "to all chirurgens of the city, that when they are called to dress a wound, they shall ask the patient who wounded him and that information thereof be given to the schout."

In 1664 the English, under the command of Col Nicolls, the personal representative of the Duke of York, appeared in Manhattan Bay and wrested possession of the island from the Dutch. In the following year a code of statutes known as the "Duke's Laws" was enacted. One of these laws related to "Chirurgens, Midwives, Physicians" and provided, "That no person or persons whatever employed about the bodys of men, women or children, for the preservation of life or health as chirurgens, midwives, physicians, or others, presume to put forth or exercise any act con-

trary to the known approved rule of art in each mystery or occupation, or exercise any force, violence, or cruelty upon or towards the body of any, whether young or old, without the advice and consent of such as are skilful in the same art (if such may be had), or at least of some of the wisest and gravest then present, and consent of the patient or patients if they be mentis compotes, much less contrary to such advice and consent, upon such severe punishment as the nature of the fact may deserve, which law, nevertheless, is not intended to discourage any from all lawful use of their skill, but rather to encourage and direct them in the right use thereof, and to inhibit and restrain the presumptuous arrogance of such as, through confidence of their own skill or any other sinister respects, dare boldly attempt to exercise any violence upon or towards the body of young or old, one or other, to the prejudice or hazard of the life or limb of man, woman or child."

From time to time thereafter numerous statutes were enacted covering the medical profession and designed for the protection of the public health. In 1715 a law was passed exempting physicians and surgeons from performing the duties of constable or tax-collector, and fifty years later a statute was enacted exempting physicians from performing military duty except in case of an invasion.

In the same year, 1755, an act was passed to prevent "infectious distempers" from being brought into this colony and to hinder the spreading thereof. In the following year a law was passed to appropriate money raised by divers lotteries "for erecting a college and pest-house," and two years later another statute was enacted to prevent the bringing in and spreading of "infectious distempers in this colony." In 1763 a law was passed regulating the practice of inoculation for small-pox, and four years before the Declaration of Independence a statute was enacted for the better support of the hospital to be erected in the City of New York for poor and indigent persons.

The most important law of this period provided for the general regulation of medical practice. This statute, passed in 1760 by the General Assembly of the province, ordained that "no person whatsoever should practice

defendant physician. However, the matter finally came into the hands of other attorneys who instituted an action against the physician charging him with negligence in his treatment of the patient, further claiming that he had wrongfully diagnosed the patient's condition,

failed to discover the fact that she was pregnant and by his curettage had caused the death of the fetus, requiring her to submit to a further operation and subsequent treatment.

After a two day trial the jury returned a verdict in favor of the defendant physician.

---

### PERITONSILLAR ABSCESS

Actions were instituted by both the husband and the wife against a physician, the husband suing to recover for loss of his wife's services and the wife who was the patient of the defendant physician, charging negligent and careless treatment of her throat, also charging that the surgical work of the defendant physician was so negligently performed that the patient's throat was extensively injured and not improved, but generally in a worse condition than at the time of the commencement of the treatment by the defendant physician.

The defendant, specializing in laryngology, in the early part of February was called to the home of the plaintiff where he found her complaining of a sore throat. Upon examination he diagnosed her condition as a peritonsillar abscess. After properly preparing himself and the field of operation and sterilizing his instruments he made an incision in the tonsils at a point where he believed the abscess was forming, but as the abscess had at that time not gotten into a pussy condition no pus was exuded. He left the opening made by the incision and advised the patient to use hot water as a gargle to bring the abscess to a head. On the following morning he was called by the patient's husband who stated that his wife was no better. The physician advised that the hot water gargle be continued. Nothing further

was heard from this patient until the institution of a malpractice action.

A physical examination was made of the patient several months later at which time the patient stated to the examining physician that her throat had been injured and that she had suffered blood poisoning from the incision made by the defendant. She further stated that she had been suffering from a sore throat for two or three days and went to the doctor's office. That he cut out her tonsils, that she now has a heart murmur and general weakness and has lost much weight and strength and was confined to bed for about five weeks. Upon examination the physician found that the plaintiff had a mitral murmur and irregular pulse, no joints were affected and her color was good. Just above the left tonsil he found a healed scar of incision about one inch long which, at the time of examination was perfectly healed and gave no trouble. With the exception of the heart action the plaintiff appeared to be in good condition. The examining physician felt that the defendant physician had rendered the necessary and proper treatment to limit the spread of the infection which was present in the tonsil and prevent possible damage from such infection.

This action not being prosecuted by the plaintiffs, on motion of the defendant it was dismissed for lack of prosecution.

dupes to their effrontery as to employ them, or buy their pernicious compositions, not that they should frequent so beneficial a market. So amazingly easy of belief are some people in these miracle-mongers, that, as if there was something creative in the name of Doctor, seldom any other test of their skill is required than their assuming that title, so that this appellation with a competent presence of mind and a string of ready-coined cures, carefully

propagated by such as find their account in carrying on the cheat, have seldom failed of procuring traffic in New York."

Quackery then, and the desire of charlatans to prey upon credulity flourished in our State while it was still a colony of Great Britain. How the effort to combat this evil led finally to the organization of the New York State Medical Society in 1806 will form the subject matter of a later editorial.

### WRONG DIAGNOSIS OF PREGNANCY

The patient had been under the care of various physicians for some period of time. She discharged such physicians from further care and about July 1st engaged the defendant. Upon his examination this physician found the patient in a toxic condition, urine loaded with albumin, granular casts, blood and pus cells. Her menstrual history indicated that she was several days past due. A vaginal examination did not reveal any information. A diagnosis was made of nephritis, complicating an early pregnancy. Assisted by another physician and after the proper and necessary precautionary steps were taken in the preparation of the patient, on July 5th a curettage was performed under a general anaesthesia. No demonstrable fetus or placental tissue was removed. After the performance of the curettage the urine returned to normal and remained so during frequent observations during the following year. About fifteen months after the first visit the patient again consulted the defendant seeking advice as to whether or not pregnancy would be attended by danger to herself. At that time she was advised of the possibility of the return of the previous symptoms. The patient expressed a desire to become a mother and decided that she would do so at her own risk. Shortly thereafter this physician was called to the home of the patient to attend her for vomiting. At that time he found that she was several weeks past her menstrual period and showed evidence of pregnancy. He observed her for about two weeks, after which time the heart became irregular in action and albumin and casts were present in the urine. She was removed to a hospital and a second curettage performed, at which time a small mass of placental tissue was removed from the uterus with some difficulty. The patient's condition becoming poor during the course of the operation, operative procedure was discontinued. On completion of this operation the urine again cleared of albumin, vomiting had lessened and after about five days the temperature became normal.

After the operation the patient stated that she felt much improved, but complained of occasional vomiting, but after about four days no further complaints of vomiting were made. She was discharged from the hospital about two weeks after the operation. Several weeks later the patient's husband called at the physician's office, at which time he paid part of the bill and stated that his wife was in good condition. A few days later the defendant physician called at the patient's home at which time he found a nurse and the patient's aunt in attendance upon her. Another physician had been called in to attend the patient and he had advised her that she was suffering from liver trouble. On this visit the patient told the physician that she had become dissatisfied with his treatment and for that reason had called in another physician. The defendant physician then withdrew from the treatment of the patient and heard nothing from her until about three weeks later when he was called to the patient's home. At this time he was shown a fetus apparently about eight weeks in size and apparently dead for some time, which the patient stated she had passed on the previous night. She told the doctor that out of consideration for him and owing to the fact that he had previously saved her life she wanted him to see the fetus. The patient also told the defendant physician that a drugless physician of the city had, during her last attack, been called to attend and treat her.

Several weeks after this occurrence the defendant received a letter from the patient and her husband claiming that he was responsible for the expenses arising out of her last illness and that if he would send them a receipted bill for the unpaid balance which they owed him, they would be content. He made no reply to this request. This physician shortly thereafter received a request from an attorney of the city advising that the patient had put into his hands for collection the expenses which the patient claimed to have incurred by reason of the last operation and treatment. This attorney, however, would not bring suit against the

Dr Britt also discussed the relations of county medical societies to academies of medicine, and quoted the action of the Academy of Medicine of Buffalo, and of the Erie County Medical Society by which the two bodies should apportion their activities, leaving the field of scientific medicine to the Academy while the county society assumed the direction of public health activities. The two organizations had already united their two publications in a single monthly to be called the Bulletin of the Medical Society of the County of Erie and Buffalo Academy of Medicine. Dr Britt warmly commended this action as an example of the unification which is taking place among physicians and their organizations.

Dr J S Lawrence, Executive Officer of the Medical Society of the State of New York, gave a brief outline of the plans of the Committee on Public Relations, and said that the Committee had planned to hold conferences with public health organizations other than medical societies. It had held five conferences with the State Charities Aid Association, and would hold one with the State Department of Health on November eleventh. It also plans to confer with the State Department of Education, the State Department of Mental Hygiene, and the Red Cross.

Dr Thomas P Farmer, Chairman of the Committee on Public Health and Medical Education, discussed the activities of the Committee, and said that physicians are adapting themselves to the changing conditions, especially in the practice of public health and civic medicine. The most acute civic problem before physicians at present is that concerning the establishment of county health departments. That problem is a challenge to physicians—that they shall assume the leadership in its solution, and shall prepare themselves to give the proper service when the departments are established. The leadership of the physicians through their county societies is unquestioned in some counties, and is being attempted in others.

Dr Farmer also spoke of the educational work of his Committee, and said that it was prepared to provide single talks as well as courses of lectures. He urged the societies to send their requests early, so that the Committee may apportion its funds and efforts.

Dr H L K Shaw, Chairman of the Committee on Legislation, urged the county secretaries and the chairmen of legislative Committees to respond promptly to calls when the legislative session opens.

Dr Frank Overton, Executive Editor of the New York State Journal of Medicine, read a practical paper entitled "Publicity for County Medical Societies," in which he urged the secretaries of county societies to report the ac-

tivities of their societies for publication in the Journal. This paper is printed on page 1074 of this Journal.

Dr Orrin S Wightman, Editor-in-Chief of the Journal, told of some of the problems which the editors must decide immediately as they arise, especially the acceptance of news that is merely local, or ephemeral, or personal, or destructive. The Journal makes great effort to secure news that is constructive and that will inspire other county societies to activity. The publication managers wish to make a Journal which will have a real historical value twenty years in the future. The material regarding county societies is abundant, but the editors must depend on the officers to send it to the Journal.

The subject, "A County Society's Interest in Community Affairs," was presented by four speakers. Dr W M Hale, Jr, of Utica, told of the efforts of the Oneida County Medical Society to secure a site for the County Tuberculosis Hospital. A committee on a site had made a majority and a minority report. Thus the physicians were divided in opinion, and lost much of their influence. Dr Hale closed by saying "The point is that the Medical Society did not take the lead at the beginning, and is not the leader now."

Dr W M Rapp, of Catskill, described the efforts of the Green County Medical Society to devise plans for establishing a county hospital with a legacy of \$40,000 which had been left for the purpose several years ago. But the County has only twenty-five doctors, who are divided geographically, and so the members of the County Medical Society had been unable to agree on a site or even upon the necessity for a hospital.

Dr E P Orvis, Secretary of the Erie County Medical Society, described the successful efforts of the Society to secure publicity regarding the gradings of individual milk dealers, and to improve the milk supply of Buffalo.

Dr A L Madden, Secretary of the Albany County Medical Society, told of the studies made by a committee of the Society into a new source of water supply for the City, and of its cooperation with the City Board of Water Supply.

Dr J P Garen, President of the Chatauqua County Medical Society, described some of the events which led the Society to pass the resolutions which were reported in this Journal of September 15, advocating the establishment of a county health department to be conducted and controlled entirely by the County instead of by an outside subsidized agency as at present.

Dr I A Cole, Secretary of the Genesee County Medical Society, described a conference of a committee of the County Medical Society

# NEWS NOTES

## CONFERENCE OF COUNTY SECRETARIES

The Annual Conference of the Secretaries of the County Medical Societies of New York State was held on September 15 in the Ten Eyck Hotel, Albany, with the representatives of 38 counties present. The meeting was opened at 11 o'clock by the Secretary of the Medical Society of the State of New York, Dr D S Dougherty, who presided. Luncheon was served in the meeting room at 12 30, and the Conference adjourned at 4 o'clock.

Dr Dougherty, in opening the Conference, referred to the importance of the office of secretary of a county medical society, and said that a good secretary was sometimes lost by making him president of his society. Dr Dougherty also stressed the need that the secretary should keep out of the politics of his society, but that he should act as advisor in all the activities of the society.

Dr James E Sadlier, President of the Medical Society of the State of New York, gave a fifteen-minute address. He said that he had filled every office in the Dutchess County Medical Society, and that the office of secretary, which he had filled for many years, was the most important. He spoke especially of the special work of organized medicine in the field of preventive medicine. While the physicians of New York State have made great progress in the field of curative medicine, especially by the extension of hospitals into rural districts, the doctors here and there throughout the State have also engaged in public health work through their county societies. The scope of the work has been sufficiently varied and standardized to demonstrate the probability that physicians in every county will assert their leadership in all forms of activity connected with preventive medicine and public health. Dr Sadlier especially emphasized the need that every county society should have an active committee on public health and public relations so that physicians should be more than mere followers of lay public health organizations and endorsers of their plans, but should assume the leadership in forming and directing those policies.

Dr Harry R Trick, President-elect of the Medical Society of the State of New York, said that the duties of his office were not clearly defined, and were concerned with future expectancy rather than present reality. However, he has been active in visiting county medical societies and becoming acquainted with their

officers and learning the problems that are peculiar to every locality. The scope of the work of county societies is increasing at a rapid rate which becomes apparent to the officers of the State Society as they visit the county societies.

The work of the principal committees of the State Society was next described by representatives of the committees. Dr W W Britt, Chairman of the Committee on Economics, of the Medical Society of the State of New York, outlined the work of the Committee, and said that he had made studies, and gave advice along five lines:

- 1 The service of a county society to its members
- 2 The service of a county society to the officers of the State Society
- 3 The service of a county society to the public
- 4 The service which lay organizations can render to medical societies
- 5 The relations of organized medicine to the workmen's compensation law

The Committee on Economics had been especially active in the field of workmen's compensation. Last winter 150 bills on compensation had been introduced in the Legislature. These bills were of a varied and contradictory scope, and affected physicians and injured workmen in a vital manner. Yet the opinions and advice of the physicians were largely ignored because the leaders in both labor and capital had formed a prejudiced opinion of scientific medicine by their observation of a few professional men who had grafted on both the workmen and the employers. But when the representatives of the Committee on Economics had explained the point of view of the members of the medical societies, the law makers, the labor leaders, and the capitalists all assumed a more favorable attitude toward physicians.

The great variance in the policies of all the parties concerned with workmen's compensation had led to the appointment of an industrial committee composed of representatives of all the groups. Dr Britt had represented the State Medical Society in the monthly meetings which were held. The legislative bills have been discussed at length, and the opinions of the doctors have received due consideration. This industrial committee has done much to clarify the whole question of workmen's compensation.

Dr Britt also discussed the relations of county medical societies to academies of medicine, and quoted the action of the Academy of Medicine of Buffalo, and of the Erie County Medical Society by which the two bodies should apportion their activities, leaving the field of scientific medicine to the Academy while the county society assumed the direction of public health activities. The two organizations had already united their two publications in a single monthly to be called the Bulletin of the Medical Society of the County of Erie and Buffalo Academy of Medicine. Dr Britt warmly commended this action as an example of the unification which is taking place among physicians and their organizations.

Dr J S Lawrence, Executive Officer of the Medical Society of the State of New York, gave a brief outline of the plans of the Committee on Public Relations, and said that the Committee had planned to hold conferences with public health organizations other than medical societies. It had held five conferences with the State Charities Aid Association, and would hold one with the State Department of Health on November eleventh. It also plans to confer with the State Department of Education, the State Department of Mental Hygiene, and the Red Cross.

Dr Thomas P Farmer, Chairman of the Committee on Public Health and Medical Education, discussed the activities of the Committee, and said that physicians are adapting themselves to the changing conditions, especially in the practice of public health and civic medicine. The most acute civic problem before physicians at present is that concerning the establishment of county health departments. That problem is a challenge to physicians—that they shall assume the leadership in its solution, and shall prepare themselves to give the proper service when the departments are established. The leadership of the physicians through their county societies is unquestioned in some counties, and is being attempted in others.

Dr Farmer also spoke of the educational work of his Committee, and said that it was prepared to provide single talks as well as courses of lectures. He urged the societies to send their requests early, so that the Committee may apportion its funds and efforts.

Dr H L K Shaw, Chairman of the Committee on Legislation, urged the county secretaries and the chairmen of legislative Committees to respond promptly to calls when the legislative session opens.

Dr Frank Overton, Executive Editor of the New York State Journal of Medicine, read a practical paper entitled "Publicity for County Medical Societies," in which he urged the secretaries of county societies to report the ac-

tivities of their societies for publication in the Journal. This paper is printed on page 1074 of this Journal.

Dr Orrin S Wightman, Editor-in-Chief of the Journal, told of some of the problems which the editors must decide immediately as they arise, especially the acceptance of news that is merely local, or ephemeral, or personal, or destructive. The Journal makes great effort to secure news that is constructive and that will inspire other county societies to activity. The publication managers wish to make a Journal which will have a real historical value twenty years in the future. The material regarding county societies is abundant, but the editors must depend on the officers to send it to the Journal.

The subject, "A County Society's Interest in Community Affairs," was presented by four speakers. Dr W M Hale, Jr, of Utica, told of the efforts of the Oneida County Medical Society to secure a site for the County Tuberculosis Hospital. A committee on a site had made a majority and a minority report. Thus the physicians were divided in opinion, and lost much of their influence. Dr Hale closed by saying "The point is that the Medical Society did not take the lead at the beginning, and is not the leader now."

Dr W M Rapp, of Catskill, described the efforts of the Green County Medical Society to devise plans for establishing a county hospital with a legacy of \$40,000 which had been left for the purpose several years ago. But the County has only twenty-five doctors, who are divided geographically, and so the members of the County Medical Society had been unable to agree on a site or even upon the necessity for a hospital.

Dr E P Orvis, Secretary of the Erie County Medical Society, described the successful efforts of the Society to secure publicity regarding the gradings of individual milk dealers, and to improve the milk supply of Buffalo.

Dr A L Madden, Secretary of the Albany County Medical Society, told of the studies made by a committee of the Society into a new source of water supply for the City, and of its cooperation with the City Board of Water Supply.

Dr J P Garen, President of the Chatauqua County Medical Society, described some of the events which led the Society to pass the resolutions which were reported in this Journal of September 15 advocating the establishment of a county health department to be conducted and controlled entirely by the County instead of by an outside subsidized agency as at present.

Dr I A Cole, Secretary of the Genesee County Medical Society, described a conference of a committee of the County Medical Society

with representatives of the Grange over the question of medical service to the farmers of the County, especially during the winter months (See this Journal, page 1098)

The anti-diphtheria work of a county medical society was described by Dr W C Treder, Secretary of the Schenectady County Society, and Dr J P Henry, Secretary of the Monroe County Society. Both speakers described the details of the toxin-antitoxin campaigns in their respective counties.

Dr Page E Thornhill, of Watertown, described the courses in graduate education which had been conducted during the past three years by the joint efforts of the county societies of Jefferson and St Lawrence, and gave seven conclusions as follows:

1 Three months' time is needed to prepare a course

2 The union of two or more counties in rural parts of the State is an advantage in securing high-class teachers and a good attendance of doctors

3 Publicity of the courses, both inside and outside the County, is of educational value in informing the people of the unselfish interest doctors are taking in their welfare. The names of those attending the last course in Jefferson County were printed in the newspapers.

4 At least a week should elapse between

lectures in order to suit the convenience of the doctors

5 The lectures should be according to a system. The course of the Jefferson and St Lawrence counties was on obstetrics the first year, pediatrics the second, and gastro-intestinal conditions the third year.

6 The two counties reported the lectures, and sent mimeographed copies to their members.

7 Lantern slides and moving pictures are of value in the courses.

This was the second annual conference of the secretaries of the county medical societies of New York State, although the secretaries had frequently assembled in an informal way during the meetings of the State Society. The wide range of topics discussed, and the description of specific problems of individual societies make the conferences both helpful and inspiring.

The first formal conference of New York State was held on September 2, 1926, and was reported on page 798 of the September 15, 1926, issue of this Journal.

Abstracts of the description of two conferences of the County secretaries of Michigan were pointed out on page 880 of this Journal of August, 1925, and page 816 of the July 15, 1927, issue.

## MEETING OF THE SCHOOL MEDICAL INSPECTORS

Steps are being taken to hold an American Conference of School Medical Inspectors in Cincinnati on October 17th, 1927. This action has been prompted by an increasing conviction among school physicians that an organized effort should be made to stimulate greater interest by the medical profession, and to inaugurate certain measures that would insure to the work greater efficiency and to provide more and better medical leadership. Many physicians who will be in Cincinnati for the American Public Health Association

will no doubt attend the conference of school medical inspectors.

The morning session will be at the Sinton Hotel at 9 30 o'clock. At 6 00 P M an informal dinner will be served at the same place to be followed by short speeches by prominent American School Medical Inspectors. An interesting time is already assured. For further information address Dr William A Howe, State Education Building, Albany, N Y.

## RE-REGISTRATION FOR 1928

Dr Harold Rypins, Secretary of the New York State Board of Medical Examiners announces that about the first of October the State Department of Education will mail to the 17,703 licensed physicians, registered with this Department for 1927, an application card for re-registration for the year beginning January 1, 1928.

These cards should be filled out and returned to the Department without delay. They do

not require the certificate of a notary. Upon receipt of these applications the Department will send out by return mail the 1928 registration certificates.

Physicians, upon receipt of their application cards, will greatly assist in the accuracy of the 1928 list of registered physicians if they will fill them in and return them to the Department of Education as soon as they are received.

## SECOND DISTRICT BRANCH

From the Bulletin of the Medical Society of the County of Kings, September, 1927

The annual meeting of the Second District Branch will be held in Brooklyn on the evening of Wednesday, November 9th

Definite announcements of program and the like will be made within the next week or two. Present plans call for an extremely interesting District Branch meeting, which should be attended by every Long Island member of the State Society. There will be a discussion of the medical problems of public relationships and health programs. The speakers will present the work of the four county societies and the activities of one county society in which the Second District Branch is particularly interested. The evening will open with an informal dinner at 7 o'clock followed by the meeting at 8:30. Members will hear from the Committee on Arrangements and the Committee on Program in detail.

Every one is urged to mark November 9th as reserved for the District Branch meeting.

The State Society is composed of eight district branches. The Second District Branch consists of the four county medical societies on Long Island.

The President of the Second District Branch is Dr. Guy H. Turrell of Smithtown Branch, Suffolk County. Dr. Turrell has appointed a Committee on Arrangements consisting of Dr.

Thurston S. Welton, President of the Medical Society of the County of Kings, Dr. Arthur D. Jaques, Secretary-Treasurer of the Medical Society of Nassau County, and Dr. Alec N. Thomson, Secretary Kings County's Public Health Committee.

Plans for the November meeting were formulated at a Committee meeting of the Branch officers who met with Dr. Turrell at Nassau County Court House, Mineola, on September 12th.

At the time of going to press Dr. Turrell had not appointed the Program Committee but it was the sense of the meeting that the program to be provided should include very brief descriptions of public relation and health activities of each of the District Branch constituent societies and a speaker who would explain the problem which has confronted one of the county societies not in the Second District Branch and describe the method of solution. In addition, it is planned to provide an illustrated talk by a prominent medical traveler.

An enjoyable, entertaining and profitable evening is to be provided. An evening devoted to the better understanding of the medical profession's individual, collective and community interest in health and welfare activities.

Do not forget November 9th

---

## STEUBEN COUNTY

The Medical Society of the County of Steuben held its Fall meeting at the Hornell Country Club on September 13th.

Dr. Harry R. Trick, President-elect of the Medical Society of the State of New York, made an address on the work of the State Medical Society, which was much appreciated.

The question of the Cattaraugus County Health Demonstration was discussed briefly by Dr. I. C. Munson, President of the County Society and Dr. Harry R. Trick. Much interest was taken in the controversy between the County Medical Society and the State Charities Aid Society.

Although no vote was taken, the general opinion seemed to be in favor of the stand taken by the Cattaraugus County Medical Society.

Dr. Homer J. Knickerbocker, of Geneva, presented a paper on the "Silent Gall Bladder" which he said was not silent. The paper was illustrated by X-ray films which were demonstrated by Dr. W. E. Achilles of Geneva.

Dr. D. C. McKenney of Buffalo presented a paper on Colitis and Dr. J. M. Swan of Rochester made a few remarks on the cancer problem.

I. W. BREWER,  
Secretary

---

## THE CATTARAUGUS COUNTY MEDICAL SOCIETY

A regular meeting of the Cattaraugus County Medical Society was held at Olean on September 20, 1927.

In addition to guests from the neighboring county of Allegany, twenty-five physicians were present.

A brief business session was held. Reports on receipts to the special fund of the Society were read.

The Committee on Public Health and Public Relations gave a brief résumé of its activities, and called for more suggestions in its task of de-

with representatives of the Grange over the question of medical service to the farmers of the County, especially during the winter months (See this Journal, page 1098)

The anti-diphtheria work of a county medical society was described by Dr W C Treder, Secretary of the Schenectady County Society, and Dr J P Henry, Secretary of the Monroe County Society. Both speakers described the details of the toxin-antitoxin campaigns in their respective counties.

Dr Page E Thornhill, of Watertown, described the courses in graduate education which had been conducted during the past three years by the joint efforts of the county societies of Jefferson and St Lawrence, and gave seven conclusions as follows:

1 Three months' time is needed to prepare a course

2 The union of two or more counties in rural parts of the State is an advantage in securing high-class teachers and a good attendance of doctors

3 Publicity of the courses, both inside and outside the County, is of educational value in informing the people of the unselfish interest doctors are taking in their welfare. The names of those attending the last course in Jefferson County were printed in the newspapers.

4 At least a week should elapse between

lectures in order to suit the convenience of the doctors

5 The lectures should be according to a system. The course of the Jefferson and St Lawrence counties was on obstetrics the first year, pediatrics the second, and gastro-intestinal conditions the third year.

6 The two counties reported the lectures, and sent mimeographed copies to their members.

7 Lantern slides and moving pictures are of value in the courses.

This was the second annual conference of the secretaries of the county medical societies of New York State, although the secretaries had frequently assembled in an informal way during the meetings of the State Society. The wide range of topics discussed, and the description of specific problems of individual societies make the conferences both helpful and inspiring.

The first formal conference of New York State was held on September 2, 1926, and was reported on page 793 of the September 15, 1926, issue of this Journal.

Abstracts of the description of two conferences of the County secretaries of Michigan were pointed out on page 880 of this Journal of August, 1925, and page 816 of the July 15, 1927, issue.

## MEETING OF THE SCHOOL MEDICAL INSPECTORS

Steps are being taken to hold an American Conference of School Medical Inspectors in Cincinnati on October 17th, 1927. This action has been prompted by an increasing conviction among school physicians that an organized effort should be made to stimulate greater interest by the medical profession, and to inaugurate certain measures that would insure to the work greater efficiency and to provide more and better medical leadership. Many physicians who will be in Cincinnati for the American Public Health Association

will no doubt attend the conference of school medical inspectors.

The morning session will be at the Sutton Hotel at 9 30 o'clock. At 6 00 P M an informal dinner will be served at the same place to be followed by short speeches by prominent American School Medical Inspectors. An interesting time is already assured. For further information address Dr William A Howe, State Education Building, Albany, N Y.

## RE-REGISTRATION FOR 1928

Dr Harold Rypius, Secretary of the New York State Board of Medical Examiners announces that about the first of October the State Department of Education will mail to the 17,703 licensed physicians registered with this Department for 1927, an application card for re-registration for the year beginning January 1, 1928.

These cards should be filled out and returned to the Department without delay. They do

not require the certificate of a notary. Upon receipt of these applications the Department will send out by return mail the 1928 registration certificates.

Physicians, upon receipt of their application cards, will greatly assist in the accuracy of the 1928 list of registered physicians if they will fill them in and return them to the Department of Education as soon as they are received.

## MEDICAL WARES

### THE SPHYGMO-MANOMETER

A physician understands the term blood pressure to mean the pressure to which the blood is subjected in the human arteries. It is a conception in mechanics whose interpretation involves at least four elements:

- 1 The force of the heart beat
- 2 The resistance of the blood tubes, especially the smaller arteries and capillaries
- 3 The elasticity of the arteries
- 4 The volume of the blood

An instrument for measuring blood-pressure is called a sphygmo-manometer (literally, a pulse pressure measure). It indicates the blood pressure in millimeters of height of a column of mercury, but the interpretation of the findings calls for much skill and good judgment on the part of the physician.

There is a natural variation of pressure in a person within five or ten per cent due to exercise, excitement, eating and other physiological conditions. There are often variations of the pressure due to errors in the instrument. A modern blood pressure apparatus should be an instrument of precision that gives constant results. But it is often thrown into the doctor's bag with his obstetrical forceps and artery clamps, and is bounced about in his automobile over rough roads, and then the doctor finds that his patients who had high blood pressure have unaccountably improved, or others with headaches have suddenly become threatened with apoplexy. The reliability of the instrument is an important factor in taking blood pressure. A doctor desires a sphygmo-manometer that is sturdy, reliable and portable, and whose parts are easily replaceable.

The modern blood pressure apparatus is simple in design and construction and easy to operate, and yet its evolution and development have been exceedingly slow. Over one hundred types of instruments were made during the half century preceding the year 1900, and the present standards of uniformity and reliability were reached only after patient research and experimentation.

Physicians of all ages have made a crude estimation of blood pressure when they have felt the pulse in the wrist, but the first accu-

rate observations of blood pressure were made almost exactly one hundred years ago on laboratory animals by means of a manometer connected directly with an opened artery. The first practical instruments for clinical use were designed to act on the same principle as the estimation of the pulse by the finger. A small rubber bag slightly distended with air was pressed upon the artery in the wrist and the pressure required to obliterate the pulse was noted on a manometer. Other forms used a distensible rubber bag which was applied to a finger, like a glove finger, and still others used a narrow tube or band tied around the arm. But all of them had the grave defects of the crude estimation of the pulse with the finger, and the wide variation of their results prevented their clinical use.

It seems strange that a period of over two generations was required for the development of an accurate apparatus for the estimation of blood pressure by the general practitioner. The modern instrument using pneumatic compression applied to the arm was developed in the early years of the nineteen hundreds. Dr Theodore C Janeway published a text-book on the sphygmo-manometer in 1904 with the avowed purpose of making the "knowledge which is now scattered through text books of physiology, pathology, and practice, and a considerable Journal literature of twenty odd years, readily available to every physician." The book gives illustrated descriptions of the various types of instruments and their virtues. It also discusses their defects, most of which often apply to modern instruments, especially when they are abused or carelessly used.

When the reliability of the sphygmo-manometer and the uniformity of its results had been demonstrable, the use of the instrument became universal with some degree of suddenness between 1905 and 1910. No modern physician could practice medicine today without a sphygmo-manometer. A degree of the importance attached to the subject of blood pressure is reflected in the fact that physicians of the United States alone purchase more than one million dollars worth of instruments every year.

veloping a sound county health program. Letters from various parts of the State, and other states, commending the Society on its action in regard to the Milbank Demonstration, were read and appreciatively received. Preliminary figures on the poll conducted by the Committee to determine the attitude of the physicians throughout the State were presented. It was brought out that the sentiment of physicians everywhere was overwhelmingly in support of the Cattaraugus County Society in its stand. The physicians of Syracuse especially had recorded themselves as of the same opinion as the physicians in Cattaraugus County.

The following resolution was unanimously carried:

Whereas, since the time of the meeting of this Society on August 4, 1927, there has appeared in

a newspaper in this county comments relative to the action of this Society regarding the Milbank Demonstration, which may be construed as inferring that the actions of the officers of this Society, and its Committee on Public Health and Public Relations, are not in accord with the Society itself,

Be it resolved, that the Cattaraugus County Medical Society hereby record its confidence in its officers, and its Committee on Public Health and Public Relations.

The speaker of the evening was Dr. Walter Calihan, who read an interesting paper on "Some Phases of Gallbladder Surgery." Following this paper, the discussion, opened by Dr. J. Ross Allen, was substantial and of worth.

### GENESEE COUNTY MEDICAL SOCIETY CONFERENCE WITH THE GRANGE

The Public Relations Committee of the Genesee Medical Society held a conference with representatives of the Grange on Tuesday, September 6th, for the purpose of considering medical care for the rural residents of the county.

Mrs. Roy Shepard said that she had heard many instances where families were unable to get medical care in winter, especially at night. She suggested that physicians might arrange among themselves to select one of their number to be on call, and that the Grange might assist the doctors in the collection of their fees.

Dr. C. J. Whalen of Bergen said that the greatest hindrance to adequate rural care is the snow clogged highways and proposed the following resolution, which was carried:

*Be it resolved*, that members of the Stafford Grange and the Genesee County Medical Society use all possible influence with town and county officials to keep roads in a passable condition for autos during the winter months.

Dr. C. D. Pierce of Batavia said that a second difficulty in medical practice was the disinclination on the part of farmers and their families to make proper use of hospitals. Dr. C. D. Graney of Le Roy urged that the Grange use its influence to secure the hospitalization of maternity cases and offered the following resolution:

*Resolved*, that all prospective maternity patients consult and engage a doctor before the end of the sixth month and that all residents of the county affiliate themselves with the family physician.

This resolution was unanimously adopted, after considerable discussion.

Dr. C. L. Davis of Batavia said that hospitalization should be extended to cases of general sickness. He offered the following resolution which was carried:

*Resolved*, that freer use of hospital facilities be taken not only by those requiring surgical attention, but also by those requiring medical and maternity care.

Dr. J. A. Cole of Le Roy spoke of the delay in calling a doctor until night, and offered the following resolution, which was carried:

*Resolved*, that whenever possible contact with the doctor be made early in the day.

Mr. Fred Gardner, Chairman of the Grange, suggested that all families should have some simple remedies that could be used in emergency. He also suggested that the Home Bureau might educate farmer's wives in the use of the thermometer and the method of counting the pulse and respiration.

While these resolutions and suggestions may seem commonplace to many physicians, yet the action of the Genesee County physicians is of value for it sets an example which other counties might follow. It is only too true that the people are inconsiderate of the doctor and ignorant of the good which he can do them, and that they call the doctor only when they become panic stricken and demand his attendance immediately. Grangers and Home Bureaus can do a great work by confidential cooperation with the county medical societies in educating the people regarding the assistance which a doctor can render them. The organizations have it in their own power to solve the problem of the medical aid to the rural districts.

No modern physician could practice medicine today without a sphygmo-manometer. A degree of the importance attached to the subject of blood pressure is reflected in the fact that physicians of the United States alone purchase more than one million dollars worth of instruments every year.

# THE DAILY PRESS

## TALKED TO DEATH

Many a doctor gets a reputation for wisdom by looking wise and keeping his tongue quiet, and on the other hand, many a one gets himself and his professional brethren into trouble by talking too much and often. Doctors may derive

a moral from the following poem by James J. Montague, quoted from the department "More Truth Than Poetry" in the *New York Herald Tribune* of August eleventh

### To A MOSQUITO

"You might, had your pride in your singing  
Not been so abiding and vast,  
Have continued the adderlike stinging  
With which you begin your repast  
You might, had you only been shy,  
Have crept 'round my arms and my head,  
And, fed to the bounds of desire,  
Gone, sated, to bed

"But though you could gain nothing by it,  
It would seem that you had to rejoice  
In a gift that you should have kept quiet,  
To wit, your shrill, odious voice  
You sang to me number on number  
As you rambled around through the flat,  
Till at last I was roused from my slumber,  
And cried 'What is that?'"

"It was then that I reached for the swatter,  
As the light pierced the blanket of gloom,  
And the chase became hotter and hotter  
As I followed you over the room  
You were swift and uncommonly wily,  
But my fury lent strength to my skill,  
Till that voice, which you thought of so highly,  
Forever was still

"No more will I hide 'neath the cover  
In the heat of a midsummer night,  
While there in the darkness you hover  
And boast of your murderous bite  
Appalling your fate, but you owe it  
To your pride in your voice, little skeet,  
Though you probably never shall know it,  
You died of conceit!"

## THE ANCESTRY OF MAN

THIS JOURNAL has utilized the frequent references to scientific discussions regarding man's ancestry to comment on the modern views of anthropologists. This department of Daily Press discussed these views last year on page 290 of the March 5th issue, on page 691 of the August 1st number, and on page 877 of the October 15th issue. The newspapers of September 1st carried front page accounts of an address by Sir Arthur Keith, President of the British Association for the Advancement of Science, and Professor of Anatomy at the Royal College of Surgeons. Dr. Keith reviewed the evidence of the theory of Charles Darwin that man's ancestors were related to those of the apes, and showed how modern discoveries had confirmed the general theory of Darwin, but had also shown that man's ancestors of a million years ago were even then men and not apes. Dr. Keith is quoted as saying

"In our time man is represented not by one but by many and diverse races—black, brown, yellow and white, some of these are rapidly expanding, others are as rapidly disappearing

"Our searches have shown that in remote times

the world was peopled, sparsely it is true, with races showing an even greater diversity than those of to-day, and that already the same process of replacement was at work. To unravel man's pedigree we have to thread our way, not along the links of a chain, but through the meshes of a complicated network

"We made another mistake. Seeing that in our search for man's ancestry we expected to reach an age when the beings we should have to deal with would be simian rather than human, we ought to have marked the conditions which prevail among living anthropoid apes. We ought to have been prepared to find, as we approached a distant point in the geological horizon, that the forms encountered would be as widely different as are the gorilla, chimpanzee and orang, and confined, as these great anthropoids now are, to limited parts of the earth's surface

"That is what we are now realizing, as we go backward in time we discover that mankind becomes broken up, not into separate races, as in the world of to-day, but into numerous and separate species. When we go into a still more remote

past they become so unlike that we have to regard them not as belonging to separate species, but different genera. It is among this welter of extinct fossil forms which strew the ancient world that we have to trace the zigzag line of man's descent. Do you wonder we sometimes falter and follow false clews?"

The New York Academy of Medicine considered the origin of man on April 7, 1927, when it held a symposium on the evolution of mind, when Dr. Frederick Tilney described the brains of prehistoric man as revealed in fossils, Dr. William A. White of Washington discussed evolution in the human adaptations to the complexity of modern life, and Dr. Henry Fairfield Osborn described the fundamental discoveries of the last decade in human evolution. These papers are printed in the August issue of the Bulletin of the New York Academy of Medicine, copies of which are available to physicians who are interested in anthropology. Of special interest are the two

diagrams which are reproduced from the Bulletin in order to show graphically the line of descent of man, the evidence of his existence in geologic ages, and the approximate times when he lived.

The evidence from which man's ancestry is derived has often come from unexpected sources. The skull of the "Piltdown" man, for example, was unearthed by the shovel of a laborer in a sand pit, and was recovered in fragments by a foreman who possessed curiosity. In all probability many similar specimens have been thrown away unrecognized. When a specimen is found, it is a common custom to show it to a physician, for he is popularly considered to be an authority on bones of all kinds. But of equal importance with the fossil specimen is an observation of the stratum of earth in which it was found, for it is the stratum that fixes the age of the specimen. It is possible that the opportunity to preserve a valuable fossil relating to man's ancestry may present itself to any physician at any time.

---

## PRIZE BABIES

When child welfare first became a recognized activity of departments of health, there arose the custom of holding baby shows and giving prizes to the most healthy baby. But their promoters soon found that health and pink cheeks and vigor were often accidents. Plumpness was often hereditary, rose cheeks were the expression of an excess of thymus secretion, and vigor did not represent resistance to infection. It often happened that a baby that was lusty and vigorous while it remained at home where it ate and slept normally, quickly succumbed to infection when it was exhibited, and was handled and kissed by infected admirers.

Baby shows have been abandoned by departments of health, except that prizes are sometimes offered to those who show the greatest gains in health. This permits the marasmus baby to take the prize, and is a real incentive to mothers to persist in the hygienic care of their sick babies.

A popular feature at country fairs is a modification of the healthy baby show wherein prizes are given for the baby with the best disposition. The judge and tester takes the babies in turn and puts them through acrobatic stunts and awards the prize to the one who endures the abuse the longest time without crying. Babies like to romp and sometimes the tester has to resort to covert pinches to eliminate the candidates.

Asbury Park put on its annual baby parade on August 31 in the presence of 150,000 onlookers. One hundred prizes were offered ostensibly to the babies, but in reality to the mothers who made up the babies to represent characters after the

manner of movie actors. Hygeia played but a small part in the baby show, except that she was ignored and thrust into the background amid the excitement and fatigue of the parade.

The New York *Herald-Tribune* of August 31 contained unique editorial comments on the Asbury Park parade, and said:

"We have never known a baby champion in adult life, at least consciously. Nevertheless it is not hard to believe that if he or she is aware from hearsay of the glory that crowned the infant head, he or she feels no temptation to boast of it. Quite the contrary. Every one has had friends who liked to relate that when they were born the doctor told their parents they weren't worth raising, or that as children they were so sickly their lives were despaired of. This is a natural form of vanity, since the comparison implied is very flattering.

"These folk say in effect: 'Look at me now and see what I have become despite such a poor beginning.' But who wants to say: 'I was the champion baby of the Jersey coast in the year umpty-um and now look at me?' We all shy from anticlimaxes.

"To-day, we learn, twenty-seven winners of baby parades throughout the country will compete for the title of champion baby of America at Asbury Park. At this distance and in advance we commiserate the winner and congratulate the mother."

# BOOK REVIEWS

**THE CLINICAL INTERPRETATION OF BLOOD CHEMISTRY**  
By ROBERT A. KILDUFFE, A.B., A.M., M.D. 12mo  
of 186 pages Philadelphia, Lea and Febiger, 1927  
Cloth, \$2.50

This little volume is intended as a guide for the general practitioner. Although written in a very simple style and embodying but the elements of the subject, it is very complete.

As a handy little volume for the general practitioner whereby he can keep himself acquainted with the indications for treatment as pointed out by the results of chemical examinations of the blood, it should prove a valuable companion.

MAX LEDERER

**BACTERIOLOGICAL ATLAS** A Series of Colored Plates Illustrating the Morphological Characters of Pathogenic Micro-Organisms. By RICHARD MUIR. 12mo of 134 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$4.50.

This Bacteriological Atlas consists of a series of sixty excellent colored plates collected and described by Richard Muir. The plates are the handiwork of the author and although inclined to be somewhat schematic they form excellent representations of the bacteria illustrated.

This work should prove of exceptional value to the beginner in bacteriology.

MAX LEDERER.

**THE HARVEY LECTURES** Delivered Under the Auspices of The Harvey Society of New York. Series XXI, 1925-26. By Dr. F. R. NAGER, and others. Octavo of 229 pages. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$4.00.

The Harvey Society has for its object the diffusion of scientific knowledge of anatomy, physiology, pathology, bacteriology, pharmacology, and physiological and pathological chemistry, through the medium of public lectures by men who are workers in the subjects presented.

The present is the twenty-first volume of the lectures, and contains seven monographs.

First, On Some Recent Otological Problems, by Dr. F. R. Nager, Lecturer on Oto-Rhino-Laryngology, University of Zurich, Switzerland.

Second, The Dynamics of Pepsin and Trypsin, by Dr. John H. Northrop, The Rockefeller Institute, New York.

Third, The Transformation of Mononuclear Blood Cells into Macrophages, Epithelioid Cells, and Giant Cells, by Dr. Warren H. Lewis, Department of Embryology, Carnegie Institution of Washington.

Fourth, The Parathyroid Glands, by Dr. J. B. Collip, Prof. of Biochemistry, University of Alberta, Edmonton, Canada.

Fifth, Empiricism and Rationalism, by Dr. Edwin B. Wilson, Prof. of Vital Statistics, Harvard University School of Public Health.

Sixth, Historical Outline of Medical Therapy, by Dr. Knud Faber, Prof. of Medicine, University of Copenhagen.

Seventh, Comparative Anatomy and Neuropathology, by Dr. B. Brouwer, Prof. of Neuropathology, University of Amsterdam. (Four of the above are by residents of countries other than the United States.)

The Society stands for excellence in all its publications, and it is considered a great honor to be chosen to lecture before the Harvey Society.

WM. HENRY DONNELLY

**SAUNDERS' CATALOGUE DESCRIBING 250 MEDICAL BOOKS.**

The new Illustrated Catalogue, just issued by W. B. Saunders Company, medical publishers of Philadelphia and London, describes and illustrates more than 250 titles. Of these, 42 are new books and new editions not described in the former issue of their Catalogue.

A serviceable feature of Saunders' Catalogue is the giving of the month and year of publication of each book listed. This, together with the description and in many cases the table of contents, author, his teaching connection and price, makes the Saunders' Catalogue one of unusual value from which the doctor may select and order his medical books.

There are a number of new books in the Catalogue which deserve the particular attention of progressive physicians and surgeons. For instance, there are Cecil's new Text-book of Medicine, Stokes' Clinical Syphilology, Kolmer's Chemotherapy, Morse's Pediatrics, Ford's Bacteriology, Young's Urology, Rehfuess' Diseases of the Stomach, Wechsler's Clinical Neurology, Palfrey's Specialties in General Medicine, etc., etc. Anyone desiring a copy of this 80-page Catalogue need but indicate his wish to Saunders Company and one will be sent him immediately. It is worth having in the library as an index to current medical literature.

**GYNCOLOGICAL DIAGNOSIS AND PATHOLOGY** By A. H. F. BARBOUR, M.D., and B. P. WATSON, M.D. 3rd Edition, reprinted. Octavo of 223 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$4.00.

Pathology in its relation to physical signs forms the basis of this little volume. The various pathological changes which occur in the generative tract are briefly discussed, with short paragraphs on the anatomy and histology of the parts, and a brief story of the etiology, symptoms and physical diagnosis is good. Although the book professes to be nothing more than an abstract, it is rather surprising to find no mention of Sampson's epoch making work on the life history of chocolate cysts.

C. A. G.

**VENEREAL DISEASE ITS PREVENTION, SYMPTOMS, AND TREATMENT** By HUGH WANSEY BAYLY. M.C. 3rd Edition. Octavo of 242 pages, illustrated. London, Faber and Gwyer, Ltd., 1927. Cloth, 10/6.

This is a very excellent little monograph and covers the subject matter concisely but thoroughly. While it obviously makes no pretence to compete with larger books, it fills a very definite place and is most heartily recommended to the general practitioner as a handbook of ready reference in his daily work.

N. P. R.

**PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES** For Medical Practitioners and Students. By David Lees, D.S.O., M.A., M.B. 12mo of 605 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$5.00.

The opening chapters of this book deal with syphilis from every angle and it covers this very large subject in a very concise and thorough manner.

These chapters alone are worth the price of the book. The present reviewer is not so enthused about the chapters on gonorrhea and its complications.

There is also a chapter on gonorrhea in the female.

N. P. R.

**THE MEDICINE MAN** Being the Memoirs of Fifty Years of Medical Progress By E C DUDLEY M D Octavo of 369 pages, illustrated. New York, J H Sears and Company, Inc., 1927 Cloth, \$3 50

"The Medicine Man" by Emilius Clark Dudley is an autobiography, and as Karl Edwin Harriman expresses it, the book "is less the autobiography of a man, than the personal record of an era in our American life and the concurrent progress of the science" of medicine.

In this book we get a kaleidoscopic picture of the various phases in the development of medical education and the concomitant progress in medicine. Dr Dudley can well portray for us the changes from the old time septic surgical technique when surgeons performed operations in street clothes and cared more for the æsthetic cleanliness than for the aseptic purity of their operating rooms and instruments, to the present aseptic surgery with its beautiful operating rooms, sterilizers, gowns, gloves, and sterilized instruments, for he lived through these changes.

Throughout the book we are impressed with the strong, forceful character of the man. Dr Dudley knew what he wanted and went after it, and what is more important, got it. It is no far stretch of the imagination to visualize him as an excellent surgeon, a good teacher, and an excellent administrator. He does not strike one as an exceedingly modest man and yet peculiarly he does not boast about his own achievements.

There is one flaw in the book that is outstanding and this really would detract from the book, if it were not so well written and so interesting, and that is the faulty proofreading and at times grammatical blunders.

WM RACHLIN

**BIRTH INJURIES OF THE CENTRAL NERVOUS SYSTEM**  
Part 1—Cerebral Birth Injuries By FRANK R. FORD  
Part 2—Cord Birth Injuries By BRONSON CROTHERS and MARIAN C. PUTNAM. Octavo of 164 pages illustrated. Baltimore, The Williams & Wilkins Company, 1927 Cloth, \$4 00 (Medicine Monographs, Volume XI)

During the past few years, the results of the efforts of such men as Cameron, Capon, Henkle, Weyhe, and many others interested in this vastly interesting and important subject of Birth Injuries, have been valuable contributions to this particular field of medical science. Part I, devoted to cerebral birth injuries, includes data which is the product of research work of over one hundred obstetricians. To determine whether, in the cause of hydrocephalus, birth injury has any importance, the writer has analyzed over one hundred autopsies of hydrocephalus. It is surprising to note that the relation of cerebral birth injury to mental defection, is amazingly small. Tredgold states that not more than 15 per cent of all idiots can be traced to birth injury, and these are invariably epileptic. In Part II, there are many cases of cord birth injury outlined. In view of the fact that material on this subject is extremely difficult to obtain, it being contained in special journals of obstetrics, pathology, orthopedics and neurology, the authors have offered a surprising amount of facts for the use of practising obstetrician and neurologist. We do not hesitate to highly recommend this book to the physician interested in this branch of medicine.

M L A.

**AN ILLUSTRATED GUIDE TO THE SLIT-LAMP** By T HARRISON BUTLER, M.A. D.M. Quarto of 144 pages, illustrated. New York and London, Oxford University Press, 1927 Cloth, \$9 00 (Oxford Medical Publications)

English works on Ophthalmological subjects and particularly those put out by the Oxford Press, seem to

have a happy style of diction which makes them very easy and attractive reading. This feature makes a strong contrast with translations, particularly noticeable in such technical descriptions as are presented in the slit-lamp studies.

T Harrison Butler in "An Illustrated Guide to the Slit-Lamp" certainly has attained an attractive and lucid manner of presenting the involved aspects of this new procedure.

As he states, his work does not pretend to be a complete treatise—it is a sort of introductory work and should be considered as a supplement to the book by Koby and so in turn to the Atlas of Vogt.

In this the most recent work it is interesting to note certain additions to the "Methods of Illumination"

- 1 Diffuse Illumination
- 2 Direct Focal Illumination.
- 3 Retro-illumination (transillumination)
- 4 Indirect Lateral Illumination
- 5 Sclerotic Scatter
- 6 Illumination in Mirror Light.
- 7 Oscillatory Illumination.

The discussion of corneal conditions is particularly interesting and takes up the numerous problems we meet in our every day work.

The arrangement of the section on the "Lens" particularly on the "Normal Lens," seems to lack definite logical arrangement but the author leaves a clear impression which makes up for any lack of conventional order perhaps.

The writer appends a number of pages relative to the use of the slit-lamp for unusual purposes. He speaks of its use in producing the hemianopic pupillary reaction (we must first agree that such a test would be of value), and there is a short section on the medico-legal aspects of slit-lamp microscopy. The application of slit-lamp methods to the ordinary institutions is of value as he takes it up.

One realizes the value of the truly wonderful plates in Vogt's Atlas when studying other works, and how unsatisfactory inferior illustrations are in a field where the whole problem depends on interpretation of detail. It is to be hoped that a *complete* work on this important subject will be presented before long with such illustrations as Vogt's Atlas shows, and with full elucidation of the various theories.

T Harrison Butler's book is very well-worth owning.

JOHN N EVANS

**THE HEALTH OF THE CHILD OF SCHOOL AGE.** By Various Authors. With a foreword by Sir THOMAS OLIVER, M.A., M.D. 12mo of 204 pages. New York and London, Oxford University Press, 1927 Cloth, \$1 80 (Oxford Medical Publications)

This is in book form a collection of lectures that have been delivered under the auspices of the Institute of Hygiene. The various phases of childhood are taken up by men of wide reputation in the British Isles, and they include

The Dental Problem in the School Child, Diet in Schools, Infectious Diseases in Public Schools, Eye Troubles of School Life, Preventable Deformities in Childhood, etc.

The articles are short and to the point. They give in condensed form the essence of the present day knowledge and the treatment of the conditions of the child of school age.

WM HENRY DONNELLY

# OUR NEIGHBORS

## MEDICAL PUBLICITY

Arguments for Medical Publicity are well set forth by the June Issue of *California and Western Medicine* by Dr H A Rosenkranz in his Chairman's address before the Urology section of the California Medical Association last April. The author says

"It is only by publicity that we can give the laity the information that they are seeking and that they are entitled to. If we do not explain the fundamentals of disease and health and our relation thereto to the public, the public will be served as it has been in the past by false and sectarian propaganda, thoroughly and aggressively organized on a business and paying basis with the result that the art and science of regular medicine will recede into a weakly defensive position overshadowed and encroached upon by cultists.

"The arguments that I have most frequently heard against advertising are

"1 'I have all the patients that I can take care of, haven't you?' 'Why try to get more?' It is this attitude of self-sufficient indifference that is partly to blame for our cult-ridden condition. Without building up a large practice, how can a physician acquire that amount of experience and resources necessary for the organization and maintenance of an institution where research may be carried out, medical science advanced, and the public most efficiently and economically served?

"Argument No 2 'Doctors can't guarantee their services hence shouldn't advertise.' Those of you who have tried to extract a guarantee from an automobile dealer or repair man will

readily classify the form of mind that advances this gesture

"Argument No 3 'The quacks indulge in publicity, so we shouldn't do it.' Would you interdict the sale of the Bible because some one else is circulating dime novels?

"Argument No 4 'It isn't nice to advertise—isn't done.' Perhaps the moving-picture industry sensed this very bad taste when it discontinued its 'advertising department' and substituted a 'publicity department.' The name was changed and everybody was happy. A constructive truth needs no apology. Life and health are important subjects. We physicians have assumed a responsibility in treating the sick who come to us, and we also owe to the public such information as will make most available and effective the methods of preserving health and life. Our shrinking modesty has resulted too often in the patient being forced to obtain his information on these subjects from irregulars whose blatant, subtle and destructive propaganda is always available.

"Ours is an old and glorious heritage, ever seeking the new in science and invention to apply to the healing of mankind. Are we not discriminating against the laity as well as against ourselves when we permit the public to give us the same classification and rating as the irregulars who have decreed that one minute of their education is equal to one hour of ours?

"Cannot we inaugurate a middle road of dignified publicity, thereby maintaining a higher degree of order within our own ranks and clearing up the confusion that exists in the minds of the laity?"

## THE DOCTOR'S CIVIC OBLIGATIONS

The Medical Society of the State of New York is not alone in setting forth the civic duty of its members. This was the subject of the inaugural address of Dr W R Calderwood, President of the Utah State Medical Association. The address is printed in the September issue of *California and Western Medicine*, from which the following extracts are taken—EDITOR'S NOTE

"Every organized body of men owes certain specific and definite duties to the community of which it forms a part and from which it derives its protection and is enabled to function as an organization

"All of our illustrious predecessors in the field of medicine, those to whom we point with pride and honor as the great leaders in the alleviation of human suffering and the prolongation of human life, have had a keen sense of the obligation they owed society and the opportunity afforded them to serve their fellowmen.

"The achievements of organized medicine have not been surpassed by any other group of workers in the world's history. While we point with pride and satisfaction to past achievements, we realize that new and equally important problems require our most earnest

(Continued on page 1106 adv xvi)

(The Safe Milk)

# IDEALLY ADAPTED

FOR THE

# MARASMIC INFANT!

*P*EDIATRISTS generally agree that the food given the *marasmic* infant must be exceptionally concentrated because the vigor and stomach capacity are both inadequate for the ingestion of large volumes of food. The food, too, must be of such a balance that it will supply the needed nutrients in proper proportion. The most important consideration is the selection of a food that is readily digestible since the digestive capacity is unquestionably subnormal.

This combination of a concentrated food of proper balance, high caloric value, which is readily digestible and completely assimilable is available to the Pediatrician in DRYCO, the safe milk in powder form. By virtue of the fact that the quantity of water may be diminished a concentrated diet of high caloric value may readily be obtained. The fineness and softness of the DRYCO curd assures its maximum assimilation and absorption with a minimum of digestive effort. In view of its palatability *marasmic* infants readily adapt themselves to DRYCO, showing at the same time, a marked improvement in appetite and weight.

(Continued from page 1104)

consideration. We cannot rest on our oars or be content to follow in the footsteps of our predecessors. New and changing conditions require new viewpoints and new angles of approach.

"The call that comes to us for a physical examination of the apparently well is but one of the new and pressing problems which we are called on not only to meet, but to foster, encourage and direct. This demand and opportunity which comes to us for a new and broader service has resulted largely from the activities of official and non-official health agencies. It is our duty to join hands with these organizations and by directing them bring about a closer cooperation and a more unified effort to serve the public in a safe, sane and scientific manner.

"There is no basic reason for differences between medical men and official or non-official health organizations—each exists in response to this same call for help coming from the same source—the great mass of humanity. We should get together, compose our differences, and with a united effort seek only the best means of bringing accurate scientific data to the solution of problems of human welfare and human happiness.

"Health organizations are established conditions. They exist in response to a public demand for help. They are factors in the complex structure of modern civilization, making for better hygienic conditions and better health, and we must accept them. We can best serve the public, as well as promote our own interests by becoming a directing force in these organizations. Dr. DeSchweinitz, past president of the American Medical Association, in a recent address, said the public could be prevented from straying down the wrong path only if the medical profession had some dignified proper method of giving out the right information in the right way. He says that the time has come in modern medicine when there must be some kind of a properly regulated publicity. The present methods are not satisfactory.

"The work being done in the field of the pediatrician where the united efforts of boards of health, lay organizations and the medical profession are being directed to health conservation, or keeping the well baby well, shows very definitely the trend of civic medicine.

"Here we see the three forces—official health organizations, lay organizations, and medical men working in harmony for the welfare of the baby.

"In the dental field like efforts have produced like results, until now the public call for help has outdistanced the dental profession and den-

tal clinics have had to be set up by boards of health or departments of education to care for the baby teeth. These clinics are established in response to a demand for help only when the dental profession fails to meet an insistent demand.

"In the field of general medicine tendencies are in the same direction. Official and non-official health organizations are using their every effort to educate the general public in health conservation.

"As a result of these efforts, we find in the daily press and in current periodicals articles treating in a scientific and dignified manner, various phases of the better health movement. We should avail ourselves of these various agencies at our disposal to facilitate public education on health problems. The daily press is not only willing but anxious to publish any worthwhile authentic health information of general interest.

"The periodic health examination is the foundation of every health program, and medical men should assist in every way possible to educate the public to its importance as well as to the fact that the family physician is well qualified to make the examination. If we fail to make use of our opportunities in this line, we are apt to see commercial agencies take over this work, as they are already doing, and we will be required to serve as their hirelings.

"The public have made possible our training. Are we repaying our obligation to them? Progress is made by trial and error, and we seem willing to let the "dear public" progress in this way. We forget that we are the recipients of all that has been learned in the school of medical experience, in past ages of trial and error, with its incalculable human sacrifices. We are remiss in our sense of duty if we fail to impart to the public this knowledge accumulated through the ages, and which we have come into possession of through their efforts in our behalf.

"The plea that I make is for a better appreciation on the part of the medical man of his civic obligations. Because of his special training he is qualified for leadership in all movements having as their purpose better health, physical or mental. All well-meant public health movements, official or non-official, should receive his support and he should be a directing force in shaping their activities and in securing cooperative efforts. The education of the public in physical and mental health should be made a business proposition with the organized medical profession."

*The Sesquicentennial Gold Medal awarded at Philadelphia as a recognition of the high quality of*

### PATCH'S FLAVORED COD LIVER OIL

At the Sesquicentennial Exposition held in Philadelphia last year, the E. L. Patch Co. was awarded the gold medal for "excellence of product."

This award is only one of the various forms of recognition which our product has received.

The recognition given to our product by the medical profession, after five years of clinical experience, constantly reminds us of our great responsibilities.

Here are a few reasons why Patch's Flavored Cod Liver Oil is dependable.

It is made in our own plants along the North Atlantic Coast, from FRESH LIVERS.

Every lot is biologically assayed. The vitamin potency is guaranteed.

The dose is small—a half teaspoonful for children or a teaspoonful for adults three times a day.

It is pleasantly flavored. Your patient will appreciate this feature.

Let us send you a trial bottle of this "Gold Medal Cod Liver Oil."

Taste it! You'll be surprised.

## KEEPING ABREAST OF THE MEDICAL TIMES

A doctor is popularly supposed to acquire progressive skill with experience but the initiated realize that experience without reading and reflection tends to fossilization. This idea is contained in the September Nebraska State Journal in an article entitled "The Mitigation of Old Fogyism" by Dr. H. Gifford, who begins in a pessimistic vein by saying:

"The development of old fogyism in medicine may be said to begin with the first year of practice. Favorable results obtained by the use of measures which the young physician has been taught, start the congealing process which, as the years roll on, develops into the mental attitude of satisfaction with tried measures that practically closes the mind to the possibility of any improvement on them. At the same time the process of disillusionment begins and the ardour with which the young doctor greets every new remedy, gradually changes to a hard-boiled skepticism. The results of these converging tendencies is satisfaction with the old and distrust for the new.

"If old fogyism gets its start in early practice, it follows that its mitigation should also get an early start. To do this, the most important thing in planning the campaign for the future medical career is to achieve an attitude of mind which makes the study and practice of medicine, not a breadwinning routine but the chief and all important source of enjoyment in life. Much 'bunk' has been written about the desirability of an avocation for professional men. For the business man, an avocation in the form of some mental exercise is undoubtedly desirable, for a physician, the avocation too frequently has a tendency to become the chief interest and enjoyment, while medicine becomes a daily grind. For a man who wishes to use his mind, nothing can or should offer greater interest than the continued study of medicine. Allowing that as a citizen, one should do a certain amount of outside reading, it will add greatly to the enjoyment of his professional life if a man can train himself to do this outside work as a duty, to which a certain amount of time is given from the main enjoyment of professional practice and research.

"Granting, however, that the practitioner is wholly in sympathy with the idea of getting his pleasure from his practice, there are two main obstacles in the attempt of an older man to keep efficient and up to date. These are, on the one hand, the immense number of new terms which are constantly being brought into medical literature. There is an inevitable tendency to postpone the exact elucidation of such terms. But this tendency should be combatted promptly.

ly and strenuously because the influence of such ignorance becomes cumulative

"If the practitioner will, beside his local and special medical journals, take one journal such as that of the American Medical Association and will read it carefully and will follow up the side lines which it opens, he will thereby become a far better posted man than nine-tenths of the men with whom he comes in contact

"With regard to the time which a man ought to devote to his medical reading, this must necessarily be a personal equation. If the physician is thoroughly in sympathy with the idea of getting his chief pleasure from his profession, no difficulty will be encountered in putting in sufficient time. Otherwise, the temptations of outside distractions may seriously curtail his reading hours. The writer has found that by devoting at least a single hour every evening to medical work, one can go a long way toward keeping up with the times. But the allotted period must be filled with unfailing regularity, or, if emergencies interfere, the lost time must be made up. If such a rule is adopted it will be found that inclination will lead the reader to far over-run his time

"One of the most discouraging features of

practice, in advanced years, is the facility with which important cases, which would have produced indelible impressions in earlier years, slip out of the mind as if they had never been. To guard against this, it is important to keep an indexed list of peculiar or important cases and to review these several times at short intervals. I emphasize the importance of short intervals in all these repetition aids to memory, because if longer intervals are employed, a dent made by the first impact may be completely effaced before the second is brought to bear and it thus has no more effect than the first one

"Aside from the continued necessity of earning a living, for most men, the main justification for the continuation in practice after the sixty-fifth year, consists in their having accumulated a store of experience, which, combined with a reasonable amount of clinical acumen enables them to give as good or better practical service than many younger men. All the more reason then for men who are passing the meridian to increase this valuable asset of later life by making an extra effort to fasten in their minds not only their own cases but those of which they read. Illustrated cases, can, of course, be more easily remembered and pictures should be given special study to this end"

## COLORS DENOTING PROFESSIONS

The *Journal of the Michigan State Medical Society* now appears in a green cover. Its July issue contains an explanation for the choice of green. It quotes the following table given an English manufacturer of gowns to show the colors appropriate to the professions

### DEPARTMENTAL COLORS

Arts and Letters	White
Theology and Divinity	Scarlet
Laws	Purple
Philosophy	Blue
Science	Golden Yellow
Medicine	Green
Pharmacy	Olive
Dentistry	Lilac
Veterinary Science	Gray
Fine Arts	Brown
Music	Pink
Library Science	Lemon
Pedagogy	Light Blue
Forestry	Russet
Commerce and Accountancy	Drab
Engineering	Orange
Physical Education	Sage Green
Humanics	Crimson
Oratory	Silver Gray
Public Health	Salmon Pink
Agriculture	Maize
Economics	Copper

"These colors please the eye and delight the beholder. They add immensely to the beauty and impressiveness of the ceremonial processions. The arrangements of the colorings excite the interest of the spectators who try to figure out the full significance of the symbolic display and to determine by colors the colleges participating.

"The colors selected for the different degrees are historic, appropriate and easily remembered. The white for arts and letters comes from white fur of the Oxford and Cambridge B.A. hoods, while the red for divinity follows the traditional color of the church, signifying burning love and zeal for the faith as used by Cardinals for centuries. The purple for laws comes from the royal purple of the king's court, the blue of philosophy is the heavenly color that betokens truth and wisdom. The green of medicine comes from the green stripe of the army surgeon's uniform—originally, perhaps, the color of medical herbs allied to which is the olive of pharmacy. The golden yellow of science speaks of the wealth of scientific discovery and invention. The pink for music comes from the pink brocade of the Oxford doctor of music.

## MALARIA

Misconceptions regarding malaria are prevalent among both physicians and laymen. Dr. M. A. Fort discussed these misconceptions before the Medical Association of Georgia, on May 11, 1927, in a paper of unusual value and interest, from which the following abstracts are taken—  
*Editor's Note*

We will run over a few facts that everybody ought to know

1 Malaria is caused by little living animal beings in the blood, and by nothing else

2 This parasite is put in by a mosquito and by nothing else

3 The only mosquito that can carry this parasite is the anophele, and the only variety of anophele to be feared in Georgia is the *Anopheles Quadrimaculatus*

4 The Quads raise only in ponds, and not in running streams, tin cans, barrels, tubs, septic tanks, wells or other holes dug in the earth as the borrow pits made in road building. The clean-up campaigns for removing cans and trash are good for comfort, but they have no influence in preventing malaria

5 No ponds, no Quads, no malaria. The Quad gets her malaria from people who have malaria. A million Quads might hatch out of a pond and sting a million people, but they would not infect any of the people. But if some of the people had malaria already, the Quads would suck their stomachs full of malaria blood

6 Malaria is not transmitted in the winter in Georgia, but the parasite lives in the blood of uncured persons all winter, and when frost comes and the mosquito gets chilled the parasite will no longer develop and produce malaria, even if the mosquito is not killed. Malaria lives over winter in people, not in mosquitoes. The spring outbreaks of malaria are recurrences

of uncured cases of the year before

7 While the parasites multiply in the blood, this takes place in the blood of the spleen, and possibly in the bone marrow and other deep tissues. As Dr. Darling used to quote, "The tragedy is enacted in the spleen. In the peripheral blood we see only the overflow."

8 Some Ways of Diagnosing Malaria

*First* Enlarged Spleen. Almost any case of malaria of any severity has an enlarged spleen.

*Second* History. A person who has not had acute fever, having, at least in the beginning, a periodic tendency, with chills, probably has not malaria. Chronic malaria probably does not originate as such.

*Third* Presence of Quads, or their larvae.

*Fourth* The Microscope. When a stained blood smear is examined and the characteristic parasites are found, we have one of the most satisfactory and absolute diagnoses known to medicine. But unfortunately, we do not often find them. The tragedy is enacted in the spleen, while in the peripheral blood we find the overflow. And there is no overflow as long as the spleen is able to control the disease. Many cases having acute chills and fever and taking no quinine will show parasites, but in the vast majority of true malaria cases the microscope finds nothing. If a little quinine has been taken, the slide is nearly always negative, even with acute fever. Many doctors send a smear in, and if it is negative they say, "I have proved it is not malaria." They have proved nothing of the kind. Other doctors treat many of their cases as having a "touch of malaria," though these patients never have had an acute fever, enlarged spleen, or been exposed to Quads. These cases are not malaria."

"These colors please the eye and delight the beholder. They add immensely to the beauty and impressiveness of the ceremonial processions. The arrangements of the colorings excite the interest of the spectators who try to figure out the full significance of the symbolic display and to determine by colors the colleges participating.

"The colors selected for the different degrees are historic, appropriate and easily remembered. The white for arts and letters comes from white fur of the Oxford and Cambridge B.A. hoods, while the red for divinity follows the traditional color of the church as signifying burning love and zeal for the faith as used by Cardinals for centuries. The purple for laws comes from the royal purple of the king's court, the blue of philosophy is the heavenly color that betokens truth and wisdom. The green of medicine comes from the green stripe of the army surgeon's uniform—originally, perhaps, the color of medical herbs, allied to which is the olive of pharmacy. The golden yellow of science speaks of the wealth of scientific discovery and invention. The pink for music comes from the pink brocade of the Oxford doctor of music.

## RAT-BITE FEVER\*

Report of a Case with Demonstration of the Causative Organism and Its Use in Treatment of Paresis

By STANHOPE BAYNE-JONES, M D

From the Department of Bacteriology School of Medicine and Dentistry  
University of Rochester Rochester, N Y

THE bite of the ordinary gray rat is sometimes followed by a disease in man known as rat-bite fever, or by the Japanese term "sodoku." In this country, about 50 cases have been reported, some of which were reviewed by Crohn<sup>1</sup> in 1915. The disease is rare, but occurs throughout the world and has such a characteristic course that it is usually readily recognized. Aside from its general significance, it has, at present, two especially interesting phases: first, its etiology, and second, the use which is being made of the causative organism to produce a febrile disease in man for the treatment of paresis.

For some years, on account of the work of Schotmüller, of Tuncliff and of Blake<sup>2</sup>, it was thought that rat-bite fever was caused by a streptothrix. Since 1916-17, however, when Futaki<sup>3</sup>,<sup>4</sup> and his associates described the occurrence of a spirochete, which they called *Spirochaeta morsus muris*, in infected animals, reports of studies in Japan, Europe, Mexico and this country have confirmed their findings. Shattuck and Theiler<sup>5</sup> discovered the same organism in a case in Boston in 1924. After a review of the literature, they regarded their case as the first one in this country in which the presence of *Spirochaeta morsus muris* had been demonstrated. In 1925, this organism was found in a case in New Orleans by Lanford<sup>6</sup> and Lawson, and in Mexico by Monroe<sup>7</sup> and Mooser. The case reported in this paper is the fourth in North America to receive this etiological substantiation. The organisms occur in such scarcity in the blood and lesions of man that it is easy to understand how they might have been overlooked unless especially searched for. Although the significance of the occurrence of the streptothrices and bacteria encountered by Schotmüller, Blake and others is not yet clear, it is now well established that the disease is an in-

fection with the type of spiral organism known as *Spirochaeta morsus muris*, or as Robertson<sup>8</sup> prefers to call it, *Spirillum minus*.

I am greatly indebted to Dr Edward G. Nugent, of Rochester, for giving me the opportunity to obtain material for study from one of his patients who had rat-bite fever. Without the help and guidance of Dr Nugent, the causative organism would not have been found.

## REPORT OF CASE

The patient, J. L., (Strong Memorial Hospital, Unit No. 3924), a white man, 48 years old, was bitten on the right thumb by a rat on October 10, 1926. Nine days later, the thumb began to swell and became painful. Before his visit to Dr. Nugent, the swelling had been incised and an antiseptic applied to the wound. On October 26, 16 days after the rat bite, he had chills, fever and headache. The thumb was swollen, the axillary glands were tender, and his temperature was 104° F. Between this date and November 5, the patient passed through several periods of chills and fever, the temperature remaining elevated about 48 hours and reaching 104° F. On November 5, a large purplish macular eruption began on the right arm, and during the next two weeks this eruption appeared in spots on the arms, legs, feet and abdomen. Between the attacks of chills and fever, the patient felt quite well. Clinically, the disease was typical rat-bite fever, but treatment was withheld, with the patient's consent, until etiological studies could be made. Several blood cultures, during the period between October 26 and November 16, were sterile, except one plate which was obviously contaminated by a hard, chalky white growth of two colonies of a streptothrix commonly found in dust. This organism did not resemble any other streptothrix described in connection with this disease and was not pathogenic. Dark-field examinations of pus from the wound on

\* Read before the New York State Association of Public Health Laboratories, Niagara Falls, May 10, 1927.

## LISTER PORRIDGE POWDER

This is a starch-free, sugar-free and practically foodless powder, from which the patient can easily make a most acceptable substitute for oatmeal, farina, etc. All one has to do is to stir one ounce of the Powder into one cup of salted, boiling water. This porridge, taken with cream and such a sweetener as Listers Sugarless Sweetener, is really very palatable. The food value of a generous serving, made according to the above recipe, is as follows: Protein, 8 gram, fat, 3 gram, giving a total calorific value of six.

Medical men, as well as patients who have had an opportunity to taste Listers Porridge Powder, are enthusiastic in their praises—Adv

## AN ANNOUNCEMENT

The Radon Laboratories of the Standard Chemical Company at Pittsburgh and New York have been combined and that all shipments are now made from the company's New York Laboratory at No 1 East Forty-second Street, and the Chicago Laboratory, 25 East Washington Street. The com-

bination of the Pittsburgh and New York Laboratories enables the company, with the aid of the airmail service, to effect prompt deliveries of this important medical agent to practically all parts of the United States—Adv

## HORMONES

In the work of metabolism the hormones contributed by the various ductless glands—the endocrine chain—play the chief role. The hormone of the suprarenal gland is credited with two distinct functions, it stimulates the glycogenolytic function of the liver, and it either stimulates the sympathetic system of nerves or duplicates the effect of such stimulation on the body.

This hormone is known among physicians everywhere as Adrenalin. It is the first hormone ever isolated from any of the glands of internal secretion. Parke, Davis & Co., who discovered it on the advent of the twentieth century, gave it the name Adrenalin, signifying its derivation from the adrenal or suprarenal glands.

In order to make sure of obtaining the original product, physicians are advised to designate it by its

original name—Adrenalin. See advertisement ad page XXI—Adv

## SPIRELLA MATERNITY CORSET

Through the courtesy of clients and physicians the Spirella Designer has had an opportunity to study the Spirella Maternity Corset on many figures during the different periods of pregnancy and has been able to design the garment to meet the actual demands put upon it during the time of its use.

Many women, slender, medium and stout, have worn and are wearing the Spirella Maternity Corsets and finding them comfortable and serviceable during the entire period, and their physicians have given these corsets their hearty approval.

The Spirella Maternity Corset was demonstrated before the physicians during the Medical Convention held at Niagara Falls, New York. Obstetricians commended the principle of the sling support and the contacts formed have enabled many more women to receive this valuable Spirella Service. See ad page XI—Adv

imals 5 to 15 days after inoculation, and are persistently present until the animal dies. White mice exhibit no symptoms or lesions, but have the spirochetes constantly in their blood stream. Mice thus harboring the organism have been kept from 6 to 11 months, providing a convenient source of infectious material.

The organism has a short spiral body, 2 to 7  $\mu$  in length and is apparently considerably wider than other pathogenic spirochetes. Some forms are short having only two coils, others are longer having 4 to 6 coils, with the crests about 1  $\mu$  apart (Figs 1 and 2). One or more flagella, 2 to 4  $\mu$  long, occur at each pole (Figure 3). Adachi<sup>11</sup> and others have described branched flagella, but I have never seen that formation. Occasionally, flagella appear at the sides of the middle of the longer spirals, probably at points of division. The motility of the organism is an extraordinarily rapid rotating and darting movement in straight paths. During this movement and also at rest, the body seems to be rigid like that of a bacterium. Wright's stain, other stains used for hematology and silver impregnation methods are most satisfactory for coloring the organism. The position of this microorganism is not yet definitely determined. Some authors, regarding it as related to the bacteria, have named it *Spirillum minus*. As satisfactory cultures have not been obtained, these questions cannot be settled at this time. But from the nature of the infection it causes, the sensitivity of the organism to salvarsan, and other features, it seems to be more closely allied to the spirochetes, as was indicated by the name *Spirochaeta morsus muris* given to it by its discoverers.

Fig 3—Photomicrograph of spirochete showing single flagellum at each end. Modified Fontana stain.

#### TREATMENT

In 1912, before the discovery of the organism, Hata<sup>12</sup> introduced salvarsan therapy for the cure of this disease. Since then, that drug and similar arsenicals have been used for their specific

and rapid effect. Cure follows promptly upon the injection of any of the arsenicals of this type, in the usual doses. One injection is often sufficient to put an end to the fever and cause a rapid disappearance of the lesions.

Fig 4—Photograph showing macular skin eruption on trunk and arms of Patient C, a paretic, who was given rat-bite fever for the therapeutic purposes.

#### USE IN TREATMENT OF PARESIS

Experimentally produced "sodoku" has been employed by Solomon<sup>13</sup> and his associates to produce paroxysms of fever for the treatment of paresis. As contrasted with the malarial parasite, used for this purpose, the organism of rat-bite fever offers several advantages. It produces a relapsing type of febrile disease, with temperature elevations as high as 104° to 105° F when injected intracutaneously into the skin of the thigh in man. Intravenous injections also cause infection. The disease in man thus produced is not dangerous to the life of the patient, and can be stopped promptly by arsphenamine. The disadvantages are the skin lesions. At the site of inoculation, a large ulcer covered with a dry black scab and surrounded by a zone of redness and swelling forms after the first week and persists during the infection (Figure 5). Eight to 10 days after the inoculation a macular, purple, slightly scaly eruption appears on the surfaces of the body, arms, legs, neck, parts of the face and in the scalp (Figure 4). These lesions are conspicuous, but are not painful and disappear without leaving scars after the injection of arsphenamine. The lesion at the site of inoculation can be avoided by careful intravenous injection, protecting the tract of the needle puncture from direct infection.

the thumb, of the patient's blood and of fluid from a lymph node puncture were negative, and guinea pigs inoculated with the blood did not develop the disease. Finally, on November 17, one of the macular skin lesions on the abdomen was excised, ground up and injected into a guinea pig. The causative organism was obtained from this inoculation.

The patient's Wassermann reaction was positive, giving complete fixation with both cholesterinized and alcoholic antigens, and the Kahn test with his serum was also positive. He gave no definite history or signs of syphilis. But from the persistently positive Wassermann reaction with his serum, in contrast with the usually negative results of this test in rat-bite fever, it is now thought that he may have an obscure luetic infection.

On November 20, he was given an injection of 0.6 gm of arsphenamine, after which he had one brief febrile period followed by the disappearance of the lesions and symptoms.

In December, it was discovered that the patient had glycosuria after eating a large meal. This, and other conditions which have developed in his case, are thought to be distinct from his rat-bite fever.

#### WASSERMANN REACTION

The Wassermann reaction has been negative in the few reported cases in which the results of this test have been recorded. Blood serum from guinea pigs in the early and late stages of the experimental disease has always given a negative Wassermann reaction. It seems justifiable to conclude that rat-bite fever does not cause a positive Wassermann reaction.

been examined. Joekes<sup>9</sup>, however, found it in a quarter of the wild rats which he examined in London. In Mexico Mooser<sup>10</sup> found the organism in the conjunctival secretions of rats, which always had lesions of the eyes when infected. It seems entirely probable that the organisms pass from the eyes into the mouth and hence are transferred by the teeth into the wound when the animal bites. It has been noted that when a rat bites several times, only one of the wounds goes through the changes characteristic

Fig 2—Photomicrograph of organism in a different field of the same preparation. This shows the short form of the spirochete. Wright's stain.

of the initial lesion of rat-bite fever. The organisms, therefore, do not seem to be numerous in the animal's mouth, and are probably wiped off the teeth in the first wound. Infected guinea pigs also develop this type of conjunctivitis, with a secretion which is infectious.

#### THE MICROORGANISM

The spirochete which causes rat-bite fever has been seen only occasionally in the blood and lymph node fluid from infected persons. The best method of obtaining it is the inoculation of susceptible animals, in whose blood one or two of the spirochetes can often be seen by darkfield illumination in each field examined. Of the laboratory animals, guinea pigs and mice are most susceptible. Rabbits and dogs are resistant. In the guinea pig, the infection runs a characteristic course, with fever, dry necrotic ulcers in the skin and scrotum or at the point of inoculation, conjunctivitis, and loss of hair around the eyes and muzzle. Guinea pigs die of the infection in about 3 months. Spirochetes occur in demonstrable number in the blood of these ani-

Fig 1—Photomicrograph of *Spirochaeta morsus muris* in blood of infected guinea pig, showing the long form of the organism. Wright's stain.

#### INFECTIVITY OF RATS

A search for *Spirochaeta morsus muris* in the rats in Rochester has been begun. It has not been found in any of the 25 rats which have

blastomycetica," in which condition some observers have found yeast cells only, while others have found mycelium as well as cells. Dermatoses due to yeast-like fungi, the thrush group, are accepted clinical entities and have been exhaustively summarized by Shelmire<sup>2</sup> in a recent communication, they are usually localized to the contact areas of the skin but occasionally disseminated over large areas as in water bed treatment, after wet dressings and in nursing infants. Sabouraud<sup>3</sup> has consistently opposed the conception that blastomycetes or yeast may cause intertrigos but the successful results in experimental disease reproduction by yeast auto-inoculations have effectively contradicted this opinion (recent excellent summary of inoculations by Weidman<sup>4</sup>).

#### CLASSIFICATION

The nosological position of yeast is still debated. The distinctive morphological feature of yeast is budding in tissue and culture. Castellani's<sup>5</sup> classification is the best known and most acceptable to dermatologists, in it we have first two families (saccharomyces and cryptococcus) which rarely present mycelium even in cultures. Ascospores are formed in the cultures of saccharomycetic type but no ascospores in the cryptococcus, genuine mycelium is never found in either family. These two families could collectively be called yeast or blastomycetes. Next comes a second group of these fungi, which is characterized by the presence of hyphae in addition to the usual round cell yeast structures, they embrace the other two members of the above classification, viz. endomyces and monilia, the most common causative organisms of thrush. This group of yeast like fungi might be collectively termed the thrush group in contradistinction to the non-mycelia forming division just designated as yeast. In this presentation the term yeast or blastomycetes is restricted to the status of the first group just described, i.e., no real mycelium at any time. This terminology should not confuse one with the particular yeast which Gilchrist<sup>6</sup> has described, causing the clinical entity known as blastomycosis, this fungus is a *deep* invader and was termed *Cryptococcus gilchristi* by Vuillemin.

#### PATHOGENICITY

Yeast organisms are known to inhabit the normal skin. Tommasoli<sup>7</sup> (in 1889) reported six different types of yeast species from normal skins and suggested that they might assume pathogenic properties. Greenbaum and Klauder<sup>8</sup> found 35 instances in 150 normal skins examined, finding four species which were similar to their pathogenic strains isolated from intertrigos. Other workers have found

yeast in sundry cutaneous diseases, e.g. pityriasis capitis and psoriasis, where they were considered incidental. In the face of such findings there must be close adherence to Koch's postulates. This has been done in several isolated instances with fungi from interdigital lesions inoculated in areas of like distribution. Jessner and Kleiner<sup>9</sup> performed such experiments on a larger scale than any other workers. Using various blastomycetes (Soorpilze) obtained from normal skin, 18 patients were inoculated between the fingers in various ways—on sound skin, macerated skin, lacerated skin, and macerated and lacerated skin. Results were negative on sound skin, but under the remaining conditions 40% were positive (erosio interdigitalis).

That yeast organisms are pathogenic in localized intertriginous areas, both clinical and experimentally produced instances testify, but in more extensive superficial generalized eruptions, they have been accorded but little significance if the literature is taken as a criterion. It is the purpose of this communication to particularly emphasize this manifestation. Thus, Castellani<sup>10</sup> described a condition in the tropics known as cryptococcosis epidemics, caused by the *Cryptococcus epidermidis*. It is characterized by small round patches occurring on the arms and rarely on the trunk, usually in adults. The blastomycetic elements have not been cultured. Guy and Jacob<sup>11</sup> found *Cryptococcus* in cultures in a long-standing unusual eruption of the skin and mucous membranes of a boy of six. Crust-covered lesions on an erythematous base were present around the knees and elbows and the mucocutaneous junctions of the anus and mouth were marked swelling of the lips, there was also a marginal blepharitis. Dr. Charles J. White<sup>12</sup> has recently cited two cases which he believes to be a new type of yeast infection, termed under the name of "Dermatitis Saccharomycetica," and having a rather wide distribution. The areas involved were the lateral roots of the neck, axillae, the flexure of the elbows and the groins with the primary focus in the bend of the elbow. No mention is made of cultures. Other isolated case reports are available in the bibliography submitted by Beeson and Church.<sup>13</sup>

#### AUTHOR'S EXPERIENCE

In a series of sixteen patients presenting a similar clinical picture, which ordinarily would come under the category of "eczema," involving large areas of the glabrous skin with only occasional involvement of intertriginous areas, yeast were grown on culture, all having the morphology of *Cryptococcus*. The belief that they might be of decided etiological importance, probably only in a susceptible cutaneous

The strain obtained from J L was used to infect a patient, C (Strong Memorial Hospital, Unit No 6584, Medical Service of Dr Wm S McCann), who was suffering from paresis. Typical lesions, eruption and fever were produced, and the experimental disease was promptly stopped by an injection of arsphenamine. The skin eruption disappeared almost entirely within 10 days after the injection of arsphenamine, but the local lesion on the thigh receded much more slowly.

Fig 5—Photograph of the "initial lesion" in skin of thigh of patient C, at site of intracutaneous injection of 1 cc of blood from injected guinea pig. Area of necrosis covered by black scab and surrounded by induration three weeks after injection.

#### SUMMARY AND CONCLUSIONS

1 *Spirochaeta morsus muris* was obtained from the skin lesions of a man in Rochester, New York, suffering from rat-bite fever. This is the fourth case in North America from which the organism has been obtained.

2 The spirochete has not been cultivated, but can be maintained in the laboratory in guinea pigs and mice.

3 When injected into man, the spirochete produces typical rat-bite fever, with florid skin lesions.

4 It has been used to produce a febrile disease for the treatment of paresis. No opinion on its effect upon paresis can be formed at this time. The experimental disease can be easily controlled by arsphenamine, but the lesion at the site of inoculation and the skin eruption are factors which must be taken into account in considering the application of this form of therapy.

### STUDIES IN MYCOTIC DERMATITIS\*

#### Superficial Yeast Infections of the Glabrous Skin

By CLEVELAND WHITE, MD, BUFFALO, N Y

#### INTRODUCTION

**S**UPERFICIAL cutaneous eruptions caused by yeast fungi have been noted in numerous instances in localized interdigital and other such "close contact" areas of the skin. Their etiological importance in such intertriginous der-

matites has been effectively presented by several observers, recently by Dulbrueilh and Joulia,<sup>1</sup> who reported nine cases of involvement of contact regions of the body e g inguino-crural, perianal, and inframammary. Human inoculation was unsuccessful. Interdigital infections, especially of the fingers are well known, e g the so-called "erosio interdigitalis

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 10, 1927.

blastomycetica," in which condition some observers have found yeast cells only, while others have found mycelium as well as cells. Dermatoses due to yeast-like fungi, the thrush group, are accepted clinical entities and have been exhaustively summarized by Shelmire<sup>2</sup> in a recent communication, they are usually localized to the contact areas of the skin but occasionally disseminated over large areas as in water bed treatment, after wet dressings and in nursing infants. Sabouraud<sup>3</sup> has consistently opposed the conception that blastomycetes or yeast may cause intertrigos but the successful results in experimental disease reproduction by yeast auto-inoculations has effectively contradicted this opinion (recent excellent summary of inoculations by Weidman<sup>4</sup>).

#### CLASSIFICATION

The nosological position of yeast is still debated. The distinctive morphological feature of yeast is budding in tissue and culture. Castellani's<sup>5</sup> classification is the best known and most acceptable to dermatologists, in it we have first two families (saccharomyces and cryptococcus) which rarely present mycelium even in cultures. Ascospores are formed in the cultures of saccharomycetic type but no ascospores in the cryptococcus, genuine mycelium is never found in either family. These two families could collectively be called yeast or blastomycetes. Next comes a second group of these fungi, which is characterized by the presence of hyphae in addition to the usual round cell yeast structures, they embrace the other two members of the above classification, viz. endomyces and monilia, the most common causative organisms of thrush. This group of yeast like fungi might be collectively termed the thrush group in contradistinction to the non-mycelia forming division just designated as yeast. In this presentation the term yeast or blastomycetes is restricted to the status of the first group just described, i.e., no real mycelium at any time. This terminology should not confuse one with the particular yeast which Gilchrist<sup>6</sup> has described, causing the clinical entity known as blastomycosis, this fungus is a *deep* invader and was termed *Cryptococcus gilchristi* by Vuillemin.

#### PATHOGENICITY

Yeast organisms are known to inhabit the normal skin. Tommasoli<sup>7</sup> (in 1889) reported six different types of yeast species from normal skins and suggested that they might assume pathogenic properties. Greenbaum and Klauder<sup>8</sup> found 35 instances in 150 normal skins examined, finding four species which were similar to their pathogenic strains isolated from intertrigos. Other workers have found

yeast in sundry cutaneous diseases, e.g. pityriasis capitis and psoriasis, where they were considered incidental. In the face of such findings there must be close adherence to Koch's postulates. This has been done in several isolated instances with fungi from interdigital lesions inoculated in areas of like distribution. Jessner and Kleiner<sup>9</sup> performed such experiments on a larger scale than any other workers. Using various blastomycetes (Soorpilze) obtained from normal skin, 18 patients were inoculated between the fingers in various ways—on sound skin, macerated skin, lacerated skin, and macerated and lacerated skin. Results were negative on sound skin, but under the remaining conditions 40% were positive (erosio interdigitalis).

That yeast organisms are pathogenic in localized intertriginous areas, both clinical and experimentally produced instances testify, but in more extensive superficial generalized eruptions, they have been accorded but little significance if the literature is taken as a criterion. It is the purpose of this communication to particularly emphasize this manifestation. Thus, Castellani<sup>10</sup> described a condition in the tropics known as cryptococcosis epidemics, caused by the *Cryptococcus epidermidis*. It is characterized by small round patches occurring on the arms and rarely on the trunk, usually in adults. The blastomycetic elements have not been cultured. Guy and Jacob<sup>11</sup> found cryptococcus in cultures in a long-standing unusual eruption of the skin and mucous membranes of a boy of six. Crust-covered lesions on an erythematous base were present around the knees and elbows and the mucocutaneous junctions of the anus and mouth were marked swelling of the lips, there was also a marginal blepharitis. Dr. Charles J. White<sup>12</sup> has recently cited two cases which he believes to be a new type of yeast infection, termed under the name of "Dermatitis Saccharomycetica," and having a rather wide distribution. The areas involved were the lateral roots of the neck, axillae, the flexure of the elbows and the groins with the primary focus in the bend of the elbow. No mention is made of cultures. Other isolated case reports are available in the bibliography submitted by Beeson and Church.<sup>13</sup>

#### AUTHOR'S EXPERIENCE

In a series of sixteen patients presenting a similar clinical picture, which ordinarily would come under the category of "eczema," involving large areas of the glabrous skin with only occasional involvement of intertriginous areas, yeast were grown on culture, all having the morphology of cryptococcus. The belief that they might be of decided etiological importance, probably only in a susceptible cutaneous

background, was materially strengthened by positive results in all five attempted human auto-inoculations. Recovery of the yeast in pure culture from these artificial lesions fulfilled Koch's postulates. In the patients studied, the age varied from three months to twenty-two years with eruptions of varying extent and duration. All presented at some stage thick adherent crusts on an erythematous base usually in large discrete patches. The common locations were on the face, antecubital and popliteal spaces, sides of the neck, and dorsa of the hands and wrists, sometimes involving all these regions, occasionally only one. Other less common localizations were the retroauricular, posterior cervical regions and the margins of the eyelids. Few presented interdigital foci, no mucous membrane involvement was detected in any. Several brief individual case reports will best illustrate the clinical picture, the laboratory studies pursued and the method of auto-inoculation.

M. M., a boy of thirteen presented (July 30, 1926) crusted and eroded erythematous patches on the flexor surfaces of all extremities and back of the neck with many discrete thick adherent crusting areas on the face and legs, accompanied by a variable degree of itching. Attacks had been intermittent for five years, the present was considered the most extensive. Clinically it resembled a combination of exudative type of seborrheic dermatitis and flexural eczema. The boy's general health had been excellent except for a mild attack of "eczema" of the face when a baby, he was a robust, growing school boy.

Repeated urinalyses showed only an occasional leucocyte, blood Wasserman and Kahn were negative. In two stool examinations, a small amount of fatty acid was found. They were negative for starch and ova, and positive for meat. Further detailed cutaneous examination revealed interdigital erosions of the toes quite characteristic of superficial mycotic foci. Scrapings were taken from various areas, including the toes, 10% potassium hydrate preparations were made and plantings made on Sabouraud's glucose media. In 24 hours double contoured organisms were found in the alkali preparations, especially between the toes, with an occasional budding form. No mycelia could be demonstrated, even in many subsequent scrapings. Cultures were made, and at room temperature between the sixth and tenth days two types of growths appeared on most of the planted tubes, (1) moist masses and (2) filamentous colonies with a blackish discoloration just beneath the growth. The moist masses were found to have separate and budding round and oval yeast cells with no ascospores and no mycelia. It was considered a cryptococcus and still maintains this mor-

phology (nine months time). The other growth was found by Dr. F. D. Weidman to have affinities with *alternaria*.

Auto-inoculation of (1) yeast, (2) yeast and *alternaria*, (3) *alternaria* alone, and (4) a control produced crusting lesions only where the yeast was inoculated, with no apparent exaggeration when combined with *alternaria*. The inoculations were performed on the patient's back, using a sharp scalpel and making linear incisions just deep enough to make a most superficial break in the epidermis. A small amount of serum would exude and occasionally a minute droplet of blood. No previous sterilizing was deemed advisable as the cutaneous background might have been changed thereby. Material was transferred on a sterile platinum loop from the cultures to the various minutely incised areas except the control. Loose sterile gauze was applied over the patches to prevent gross contamination from the overlying clothing. Lesions resembling the original complaint began to appear by the third day following inoculation and decidedly pronounced on the seventh day when cultures were taken to fulfill Koch's postulates. As the cultures grew faster on this planting, sufficient on the fourth day to detect the same morphological characteristics, treatment was immediately applied to the artificial lesions. The positive lesions followed the same clinical course very closely. On the second day following inoculations, there was a distinct erythematous area surrounding the transplant. Small irregular crusts usually appeared about the third day, apparently due to dried serous exudate for vesiculation was very transient if it did occur. Larger more adherent crusts became evident between the fifth and seventh days, becoming slightly more pronounced up to the twelfth day. Treatment was always instituted at this stage. Usually there was mild itching in the positive inoculations. As the *alternaria* proved to be a saprophyte on repeated inoculations, no further steps were taken to determine its species. Histological examination showed only those features compatible with any subacute dermatitis.

M. K., a boy of nine had had "eczema" all his life, with especial localization to the face with intermittent exacerbations. When first observed at the Buffalo City Hospital (Dec. 20, 1926), thick adherent crusting lesions upon an erythematous base were present on the face and back of the ears with large confluent patches of the same type on anterior surfaces of both legs. No interdigital lesions were present. General physical examinations were negative.

Blood examination showed 85% hemoglobin, 4,200,000 red cells, 15,500 white blood cells, with a differential count of 72% polymorphonuc-

lear leucocytes, 24% small lymphocytes, 2% large lymphocytes, 1% mononuclears and 1% eosinophils. The blood Wasserman and Kahn tests were negative. Blood uric acid was 3.08, creatinine, 1.15, urea nitrogen, 11.1 glucose, 106, calcium, 8.88 mg per 100 cc of serum. Two basal metabolic tests a month apart were plus 2.06 and 2.7. Urinalysis showed no abnormal changes. Histopathological examination revealed mild inflammatory changes comparable with any subacute dermatitis. Scrapings were taken for direct and cultural study. Double contoured round cells were found, with an occasional budding form. In the cultures, cryptococcus, *Aspergillus fumigatus* and *Staphylococcus albus* grew. Auto-inoculation with each of these, and both alone and in various combinations gave positive lesions only where the yeast was planted, either separately or in combination, the cryptococcus being recovered in pure culture from the produced lesions.

The three additional cases which complete the list of five will not be reviewed here in detail. In all of them positive yeast inoculation tests were obtained, the associated strains of *Penicillium brevicaulis*, *Mucor mucedo* and *Trichothecium roseum* were apparently saprophytic, judging from their failure to produce cutaneous manifestations on their respective hosts, even though the attempt was made at least twice in each case.

This series of suspected fungus cases certainly embraces more than five valid members. Eleven "positive culture" patients were not auto-inoculated because circumstances did not permit, in fact, all the cases except one were seen in office practice (in association with Dr E D Osborne). After the results obtained in the five cases first mentioned, it is probable that success would have been met in some of the eleven others.

None of the sixteen cultures has shown mycelia at any time. This is in accord with Sasakawa<sup>14</sup> who never found any gradual transformation from budding cells into genuine mycelia of the hyphomycetic sense even in yeasts which had been studied for years. Draper<sup>15</sup> has recently discovered that the round cell forms of *Oidium albicans* (one of the thrush fungi) grow as mycelia in a carrot infusion broth medium or if a small amount of inorganic phosphate is added to certain culture media, e.g. 1% peptone solution. Planting cryptococci from cultures isolated in this study into media according to Draper's methods has not produced mycelium. This would classify the cryptococci isolated in these patients as probably an autonomous group with fixed character rather than a fortuitous stage in the development of filamentous fungi which are more advanced in plant scale and might exist

at times as round cell forms and at other times as mycelium, depending on the environment, etc. Biological tests of these cryptococcus cultures are being performed to determine properties useful in a more refined classification.

The history of the case last described was that of so-called infantile eczema, and the lesions presented were characteristic of the exudative type. This would suggest a mycotic origin for at least some cases of infantile eczema. The incidence of contact reservoirs of both yeast and hyphomycetic ringworm is high in the environment of sufferers of infantile eczema, as observed by Osborne<sup>16</sup> and proven by the author in numerous instances by laboratory procedures. As an interesting illustration in this respect the following case may be cited.

J G, a boy of twenty-six months had had an intermittent eruption since the age of three months of varying extent. When first observed (Dec 1, 1926) large crusting areas were symmetrically present on the face, scalp, back of the hands, wrist, and dorsums of the feet. The mother stated that the eruption had been general at times. His general health at the time of examination was excellent, he had had rickets and nephritis, the latter accompanied by ascites, according to the history. Physical examination was essentially negative. Various types of treatment had been used apparently with little relief. A baby brother three months old had several oozing, crusting patches on the right ear, present one month. On questioning the mother, she stated that she had some skin trouble on her legs six years previously and now had some "ground itch" between her toes. Examination of the feet showed an extensive erosion with overhanging scaling borders in the interdigital space of the right foot, a lesion one would ascribe clinically to *Epidermophyton* or an allied fungus. Repeated potassium hydrate examinations from the area failed to demonstrate any mycelium but yeast organisms were constantly present. Cultures from the faces of both babies, scalp and scattered crusting patches of the older child and the mother's toe lesions developed a cryptococcus in many plantings from each area. No opportunity was afforded for auto-inoculation. Clinical analogy and positive yeast cultures would certainly point to a mycotic basis for some cases of infantile eczema, a contact reservoir focus of infection being in some member of the family—the mother in this particular instance.

#### SUMMARY

Yeast fungi of cryptococcus morphology were cultured from sixteen patients having a generally similar eruption, conforming to the clinical syndrome usually termed eczema,

background, was materially strengthened by positive results in all five attempted human auto-inoculations. Recovery of the yeast in pure culture from these artificial lesions fulfilled Koch's postulates. In the patients studied, the age varied from three months to twenty-two years with eruptions of varying extent and duration. All presented at some stage thick adherent crusts on an erythematous base usually in large discrete patches. The common locations were on the face, antecubital and popliteal spaces, sides of the neck, and dorsa of the hands and wrists, sometimes involving all these regions, occasionally only one. Other less common localizations were the retroauricular, posterior cervical regions and the margins of the eyelids. Few presented interdigital foci, no mucous membrane involvement was detected in any. Several brief individual case reports will best illustrate the clinical picture, the laboratory studies pursued and the method of auto-inoculation.

M. M., a boy of thirteen presented (July 30, 1926) crusted and eroded erythematous patches on the flexor surfaces of all extremities and back of the neck with many discrete thick adherent crusting areas on the face and legs, accompanied by a variable degree of itching. Attacks had been intermittent for five years, the present was considered the most extensive. Clinically it resembled a combination of exudative type of seborrheic dermatitis and flexural eczema. The boy's general health had been excellent except for a mild attack of "eczema" of the face when a baby, he was a robust, growing school boy.

Repeated urinalyses showed only an occasional leucocyte, blood Wasserman and Kahn were negative. In two stool examinations, a small amount of fatty acid was found. They were negative for starch and ova, and positive for meat. Further detailed cutaneous examination revealed interdigital erosions of the toes quite characteristic of superficial mycotic foci. Scrapings were taken from various areas, including the toes, 10% potassium hydrate preparations were made and plantings made on Sabouraud's glucose media. In 24 hours double contoured organisms were found in the alkali preparations, especially between the toes, with an occasional budding form. No mycelia could be demonstrated, even in many subsequent scrapings. Cultures were made, and at room temperature between the sixth and tenth days two types of growths appeared on most of the planted tubes, (1) moist masses and (2) filamentous colonies with a blackish discoloration just beneath the growth. The moist masses were found to have separate and budding round and oval yeast cells with no ascospores and no mycelia. It was considered a *Cryptococcus* and still maintains this mor-

phology (nine months time). The other growth was found by Dr. F. D. Weidman to have affinities with *Alternaria*.

Auto-inoculation of (1) yeast, (2) yeast and *Alternaria*, (3) *Alternaria* alone, and (4) a control produced crusting lesions only where the yeast was inoculated, with no apparent exaggeration when combined with *Alternaria*. The inoculations were performed on the patient's back, using a sharp scalpel and making linear incisions just deep enough to make a most superficial break in the epidermis. A small amount of serum would exude and occasionally a minute droplet of blood. No previous sterilizing was deemed advisable as the cutaneous background might have been changed thereby. Material was transferred on a sterile platinum loop from the cultures to the various minutely incised areas except the control. Loose sterile gauze was applied over the patches to prevent gross contamination from the overlying clothing. Lesions resembling the original complaint began to appear by the third day following inoculation and decidedly pronounced on the seventh day when cultures were taken to fulfill Koch's postulates. As the cultures grew faster on this planting, sufficient on the fourth day to detect the same morphological characteristics, treatment was immediately applied to the artificial lesions. The positive lesions followed the same clinical course very closely. On the second day following inoculations, there was a distinct erythematous area surrounding the transplant. Small irregular crusts usually appeared about the third day, apparently due to dried serous exudate for vesiculation was very transient if it did occur. Larger more adherent crusts became evident between the fifth and seventh days, becoming slightly more pronounced up to the twelfth day. Treatment was always instituted at this stage. Usually there was mild itching in the positive inoculations. As the *Alternaria* proved to be a saphrophyte on repeated inoculations, no further steps were taken to determine its species. Histological examination showed only those features compatible with any subacute dermatitis.

M. K., a boy of nine had had "eczema" all his life, with especial localization to the face with intermittent exacerbations. When first observed at the Buffalo City Hospital (Dec. 20, 1926), thick adherent crusting lesions upon an erythematous base were present on the face and back of the ears with large confluent patches of the same type on anterior surfaces of both legs. No interdigital lesions were present. General physical examinations were negative.

Blood examination showed 85% hemoglobin, 4,200,000 red cells, 15,500 white blood cells, with a differential count of 72% polymorphonuc-

duced by metabolism of the body as a whole, local disease, as from the nasal accessory sinuses, disease within the cranium, function headaches and headache due to afferent impulses coming in from remote parts, such as the eyes, and even as far as from the rectum. This is the plan of my paper which I shall try to develop.

In the class of mechanical headaches we are probably dealing, to a great extent, with disturbances of secretion, absorption, and freedom of flow of cerebrospinal fluid, and this in its relation to blood flow in the brain and meninges.

We can produce a headache very readily by withdrawing some cerebrospinal fluid through a lumbar puncture, afterwards allowing the patient to remain up and about. This headache is intensified if he performs exertion. It is relieved if he lies down. It is again intensified if he stoops. The headache on standing up may be due to either or both of two things. Possibly increased tension occurs in the Aqueduct of Sylvius and in the foramina of Magendie and Lushka, in its attempt to replace that removed from farther down, or, the fluid escaping down about the cord allows more blood to distend the vessels of the brain. Effort and stooping, allowing an increase of the blood content of the brain, unsupported by the balanced amounts of cerebrospinal fluid, might cause or increase the headache. The recumbent attitude apparently adjusts the balance. The localization of the headache, however, at the back of the head, would suggest the first explanation, namely pressure on the foramina and the fact that cerebrospinal fluid can be withdrawn from the ventricles in a case of hydrocephalus and no headache result, even if the patient walk about immediately, might point against the cerebral hyperaemia causing headache in good health. The question of variation of blood circulation in the brain suggested to me that one might be able to learn something about the disturbances of blood content in the head in health, and without the disturbances of cerebrospinal fluid, in the case of caisson workers and divers, and so I communicated with a number of organizations who employ men working as divers and in caissons. One might assume that the increased pressure of the water or air on the soft parts of the body could drive extra blood into the head, and I inquired if these men at any stage in their work, developed headaches. (This question, of course, did not include those entering or emerging too quickly.) The answer was that headache was not complained of under these circumstances, in health.

One other set of circumstances remains to be investigated, and that is the headache in brain tumor.

I think it is the consensus of opinion that it is only those brain tumors which block the circulation of cerebrospinal fluid from one ventricle to another that cause headache. As a rule the cranial contents are otherwise healthy in cases of brain tumor, and so it would seem that the effect of blocking the circulation of cerebrospinal fluid might be due to the compression of the brain substance or its contained blood vessels, or to the tension of the meninges. Decompression relieves the headache. This allows of great stretching of the brain substance and its vessels in the formation of the hernia cerebri, and so this process is not only painless, but affords relief. This stretching may allow of dilatation of the foramen blocked and so effect restoration of cerebrospinal fluid circulation. If so the ependymal lining of the ventricles is not sensitive to stretching, and by the same argument the leptomeninges would seem to be insensitive to stretching processes. The tension of the dura mater has been released, and the headache relieved, and yet we find the only sensitive part of a healthy dura mater would seem to be its blood vessels, and certainly the dura mater cannot be the only one of the cranial contents that can initiate pain, since it is not affected by lumbar puncture. If it be sensitive in itself or its vessels, other parts, such as the margins of the foramina must also be sensitive.

It can be demonstrated in many parts of the body that the blood vessels, arteries more than veins, are sensitive to injuries such as compression and dilatation, if these are excessive.

After removal of cerebrospinal fluid from the ventricles of a hydrocephalic, after decompression in the case of a brain tumor, in divers and caisson workers, the tone of healthy blood vessels can effect adjustments. In states of compression the vessel cannot assert any control and so must bear the full force of the mechanical disturbance.

I would suggest, therefore, that possibly compression of the blood vessels may be the explanation of headaches of mechanical origin.

Of the mechanism of the production of headache in intracranial disease, such as meningitis, it does not seem necessary for me to say much. Abscesses and gummata must cause a certain degree of headache according to the intracranial pressure they exert, but, when close to the meninges, they probably set up pain of meningeal origin. The occurrence of abscesses and gummata in the depth of the brain without pain would seem to indicate that the brain tissue itself is insensitive except near its surface. One hardly needs to speculate on the causation of headache from meningitis, either local or diffuse. It is common to all viscera that their capsules or coverings become painful during inflammatory processes.

characterized in its course in one stage by thick adherent crusts on an erythematous base. Clinically the distribution of the eruption resembled that of seborrheic dermatitis in adults and infantile eczema in the younger patients. Five attempted auto-inoculation tests produced positive lesions in the respective hosts. Two cases are reported in full to bring out the clinical picture and the experimental studies pursued.

A number of other fungi grown on culture from various patients proved to be saprophytes, judging from negative inoculation attempts, viz *Penicillium brevicaulis*, *Aspergillus fumigatus*, *Trichothecium roseum*, and a form of *Alternaria*. Bacteria of the order of *Staphylococcus albus* did not produce any manifest lesions.

Results of this study suggest that certain blastomycetes or yeast, cryptococcic in form, may be pathogenic producing widespread superficial skin infections usually designated as eczema, it is believed that some types of infantile eczema also fall into this group.

#### HEADACHE\*

By ROBERT G ARMOUR, M.D., TORONTO, CANADA

THE subject of headache is such a wide one that in a paper of this length one might easily leave out more considerations than one puts in, merely on account of the limitations of ones individual point of view. For my personal motive, I have not recently consulted any of the many excellent articles on the subject, but will endeavor here to make a contribution from my own experience and reflection.

It has seemed best, therefore, to inquire into what headache is, and what the possible mechanism of its production before considering specific aetiological causes, and this I attempt in a purely speculative frame of mind, inviting criticism and even contradiction.

Can the cranial contents be considered for this purpose, as a viscus, and can headache be compared to visceral pain? If so, the latter might be briefly described according to the teaching of that authority on sensation—Henry Head.

It will be remembered that he calls attention to the similarity of protopathic pain, sympathetic pain, deep pain and visceral pain, and it is characteristic of all of these that they are

badly localized and tend to be diffuse, that they are ill-defined, and that they are not necessarily proportionate to the strength of the impulse that produces them, where that can be approximately measured.

It has been argued by some that viscera are completely insensitive, and many of us have probably had to cut an exposed loop of bowel, and some of us have had our fingers in brain substance while actually talking to the patient, and being assured by him that he felt no pain. Yet few of us will deny that they have experienced colic, and some part of the cranial contents must initiate pain if headaches are to occur.

The bowel gives pain if tightly contracted, but not if stretched. The mucosa is insensitive unless diseased, and the peritoneal covering follows the same rule. The kidney becomes painful in a chronic parenchymatous nephritis with oedema, and this pain is relieved by splitting the capsule. Is this covering painful to stretching and peritoneum not?

The same problem will arise in connection with headache—as to what part of the organ initiates the pain. We shall have to consider mechanical factors, chemical factors as pro-

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 11, 1927

duced by metabolism of the body as a whole, local disease, as from the nasal accessory sinuses, disease within the cranium, function headaches and headache due to afferent impulses coming in from remote parts, such as the eyes, and even as far as from the rectum. This is the plan of my paper which I shall try to develop.

In the class of mechanical headaches we are probably dealing, to a great extent, with disturbances of secretion, absorption, and freedom of flow of cerebrospinal fluid, and this in its relation to blood flow in the brain and meninges.

We can produce a headache very readily by withdrawing some cerebrospinal fluid through a lumbar puncture, afterwards allowing the patient to remain up and about. This headache is intensified if he performs exertion. It is relieved if he lies down. It is again intensified if he stoops. The headache on standing up may be due to either or both of two things. Possibly increased tension occurs in the Aqueduct of Sylvius and in the foramina of Magendie and Lushka, in its attempt to replace that removed from farther down, or, the fluid escaping down about the cord allows more blood to distend the vessels of the brain. Effort and stooping, allowing an increase of the blood content of the brain, unsupported by the balanced amounts of cerebrospinal fluid, might cause or increase the headache. The recumbent attitude apparently adjusts the balance. The localization of the headache, however, at the back of the head, would suggest the first explanation, namely pressure on the foramina and the fact that cerebrospinal fluid can be withdrawn from the ventricles in a case of hydrocephalus and no headache result, even if the patient walk about immediately, might point against the cerebral hyperaemia causing headache in good health. The question of variation of blood circulation in the brain suggested to me that one might be able to learn something about the disturbances of blood content in the head in health, and without the disturbances of cerebrospinal fluid, in the case of caisson workers and divers, and so I communicated with a number of organizations who employ men working as divers and in caissons. One might assume that the increased pressure of the water or air on the soft parts of the body could drive extra blood into the head, and I inquired if these men at any stage in their work, developed headaches. (This question, of course, did not include those entering or emerging too quickly.) The answer was that headache was not complained of under these circumstances, in health.

One other set of circumstances remains to be investigated, and that is the headache in brain tumor.

I think it is the consensus of opinion that it is only those brain tumors which block the circulation of cerebrospinal fluid from one ventricle to another that cause headache. As a rule the cranial contents are otherwise healthy in cases of brain tumor, and so it would seem that the effect of blocking the circulation of cerebrospinal fluid might be due to the compression of the brain substance or its contained blood vessels, or to the tension of the meninges. Decompression relieves the headache. This allows of great stretching of the brain substance and its vessels in the formation of the hernia cerebri, and so this process is not only painless, but affords relief. This stretching may allow of dilatation of the foramen blocked and so effect restoration of cerebrospinal fluid circulation. If so the ependymal lining of the ventricles is not sensitive to stretching, and by the same argument the leptomeninges would seem to be insensitive to stretching processes. The tension of the dura mater has been released, and the headache relieved, and yet we find the only sensitive part of a healthy dura mater would seem to be its blood vessels, and certainly the dura mater cannot be the only one of the cranial contents that can initiate pain, since it is not affected by lumbar puncture. If it be sensitive in itself or its vessels, other parts, such as the margins of the foramina must also be sensitive.

It can be demonstrated in many parts of the body that the blood vessels, arteries more than veins, are sensitive to injuries such as compression and dilatation, if these are excessive.

After removal of cerebrospinal fluid from the ventricles of a hydrocephalic, after decompression in the case of a brain tumor, in divers and caisson workers, the tone of healthy blood vessels can effect adjustments. In states of compression the vessel cannot assert any control and so must bear the full force of the mechanical disturbance.

I would suggest, therefore, that possibly compression of the blood vessels may be the explanation of headaches of mechanical origin.

Of the mechanism of the production of headache in intracranial disease, such as meningitis, it does not seem necessary for me to say much. Abscesses and gummata must cause a certain degree of headache according to the intracranial pressure they exert, but, when close to the meninges, they probably set up pain of meningeal origin. The occurrence of abscesses and gummata in the depth of the brain without pain would seem to indicate that the brain tissue itself is insensitive except near its surface. One hardly needs to speculate on the causation of headache from meningitis, either local or diffuse. It is common to all viscera that their capsules or coverings become painful during inflammatory processes.

Cerebral haemorrhages would appear frequently to cause headaches when they are not profuse enough to cause coma or where the patient has regained consciousness, but the frequency with which such patients give a history of headache for a varying time before the occurrence of apoplexy would seem to confirm the suggestion that the blood vessels, especially when diseased, may be the point of origin of many headaches.

It is probable that cerebral haemorrhage also causes headache by increasing the intracranial pressure, and I am persuaded by a series of cases which I have collected, that subdural haemorrhages may cause intense headache fairly well localized and which being instantly relieved by lumbar puncture, would indicate that the tension of the dura mater causes pain, though not necessarily in itself, but possibly in its vessels. In speaking of the relief of headache in brain tumor by decompression I suggested that the sensitive part of the dura mater might be its blood vessels.

Headache is so frequently associated with disease of the accessory sinuses that very close inquiry is here indicated. This is true both of acute and chronic conditions. I would like to emphasize a statement that X-ray examination will not always indicate that local disease in the nose and its accessory sinuses exists to the degree that headache will result and so a negative X-ray should not be used to exclude this possible source of an otherwise suggestive headache.

Headache may be caused by disease of the nasal accessory sinuses by absorption of toxin by accumulation of the mucous secretion in obstructed drainage channels, and this whether the contents be purulent or merely mucous, and by negative pressure in the sinus which may be caused by turgescence of the drainage channels and subsequent absorption of the contained gases.

The increased pressure of retained secretion and the negative pressure in cases of blockage perhaps emphasize best a phenomenon to which I should like to refer again, namely the disproportion between the strength of sensory stimulus and the resulting headache.

Whatever may be our conception of the disturbance of pressure in these sinuses, most particularly the negative pressure sometimes occurring, I think we shall all agree that the headache is surprisingly severe in proportion to such a slight mechanical force, when we consider what a slight degree of pain this force would cause applied elsewhere on the surface of the body. It shows also the diffuseness which I have spoken of as being characteristic of deep pain and visceral pain.

I would emphasize again how little aid X-ray examination may give in these cases. For the

production of severe headache it is not necessary that a very thick pus should accumulate, nor that the lining membrane of the sinuses should be much thickened. I have frequently seen patients immediately relieved of headache by a nasal spray or a simple inhalation containing menthol. If these measures are followed by the blowing out of a muco-purulent secretion one feels justified in thinking that this secretion has been responsible for the headache. I would, however, further suggest that two other factors may be concerned. A flushing of the mucous membrane in its depths may relieve it of toxin and also the sedative action of the spray or inhalation may be sufficient to relieve the headache by abolishing or reducing the afferent impulses that prolong and aggravate the headache.

Perhaps I might elaborate at this point what I have suggested about slight afferent impulses causing such great pain in the form of headache. It is necessary to bear in mind that these afferent impulses must probably be continuous, since an interruption of their flow results in an immediate relief from the headache.

Another strikingly simple expedient will give at least temporary relief, but, since it is so simple, it is probably of great importance in understanding headache. I refer to the application of a cool hand to the forehead, or to massage of the scalp and such like popular remedies.

I attempt an explanation of these measures because it may lead to a better understanding of the processes at work and may be an aid to treatment. I give the explanation on my own authority, admitting that I am taking a liberty with one of Head's theories.

He points out that impairment of epicritic or superficial sensibility allows the protopathic or deep sensibility to obtrude itself as discomfort or even pain, and so ascribes to epicritic and superficial sensibility an inhibitory influence over those more primitive sensibilities. I would suggest that, in applying cold, heat, or counter irritation to the surface, we are stimulating the normal superficial sensibility to greater intensity and so again inhibiting a deep sensibility pathologically raised by disease.

One sees at times, either in operation or post mortem, great accumulations of granulation tissue between the dura mater and the cranial bones near the sinuses. These cases are characterized by long continued and severe headache which obstinately resist all forms of treatment.

Their possible existence is to be kept in mind when a case of headache apparently associated with a catarrhal process, proves intractable.

Headache in association with ear trouble is in my experience, practically non-existent. If ear disease should lead to uncomfortable sensations within the head, these are usually de-

scribed as pain, rather than headache, and tenderness of the skull is common. The importance of this observation is that pain in the head, associated with ear disease, very probably indicates an extension of the disease into the cranial cavity, and one must consider extradural abscess or brain abscess, meningitis or some such condition which cannot be treated by local measures in the ear.

In dealing with headache of functional origin one must be very careful of the use of this term. I cannot discuss it at length, but I feel compelled to say that a patient found to have a functional complaint is not to be held in any way morally culpable, in other words, his complaint is not to be considered as a deliberate fabrication.

Whether a person can truly experience pain in any part of the body without any organic cause is a matter of debate too large to discuss for the present. We are all familiar with referred pain, but that type of pain occurs on the surface of the body, and is probably never a proper term to apply to headache. I would, however, speak of a type of headache often referred to as reflex headache. Two examples of this are those from the rectum and those from the eye, of which I hinted earlier in my paper.

A person who has missed his morning defaecation may develop a headache. Later in the day, he has a movement and instantaneously the headache leaves him. This surely cannot be due to a constitutional toxæmia, the relief has been too rapid, but it must be due to some type of afferent impulse travelling from the lower bowel to the head and expressing itself there as a headache. If this be possible we must be very careful in satisfying ourselves that a headache has no organic basis.

Headache from eye strain I think comes under the same explanation. It may have at least three types of afferent impulse to cause it, either a paradoxical sensation from an overworked optic nerve, or abnormally strong afferent impulses from the internal muscle of the eyes, or the same from the external eye muscles. The latter can be very easily produced experimentally by anyone who can voluntarily hold the eyes for a very few minutes in a position of internal strabismus. It is difficult for me to express how strongly I feel about the effects of afferent impulses from different parts of the body which, under normal circumstances do not enter consciousness, but which, having been aggravated or prolonged, may produce most unlooked for results.

Many occipital headaches are caused by nervous people holding the neck, as well as perhaps the rest of the body, in a state of tension, and so creating abnormally strong deep afferent impulses. These from the eyes and

from the neck then follow the rule of deep sensations, and tend to become diffuse and poorly localized.

There is another sensation not quite accurately described as a headache, but variously described by different patients, depending on their command of language or desire for accuracy. Sometimes it is called a sense of weight or pressure instead of headache.

Almost always this is found in those who are depressed or overworked, and it is not unlike what may be experienced by one who is experiencing profound grief, excitement, or even severe and sustained intellectual work.

Perhaps we can expect of the brain, as we do of other organs of the body, that excessive use will cause local discomfort, commonly called fatigue.

Those depressed cases and worriers can certainly be relieved in proportion as their interests are drawn away from themselves and their problems, and so interrupt the mental strain.

When I speak of headaches as due to chemical changes I am not posing as a biochemist in any sense of the word, and I hope to learn from the discussion much more than I can contribute but I take the liberty of indicating a few possibilities. The simplest form of headache of chemical origin that suggests itself to us is that due to carbon dioxide poisoning as in a poorly ventilated room. Exactly how small a variation in the chemistry of the blood by this process is adequate to cause headache hardly matters. It is sufficient for us to realize that the central nervous system is very sensitive to changes in the blood composition that are not necessarily disease processes.

Abnormalities of water intake are not uncommon causes of headache. Persistent or habitual low intake is probably not a very common cause, but one or two days deprivation of water, as practised, for instance, in the concentration test of the kidneys, may cause severe headaches.

Other people complaining of habitual headaches are sometimes found to have adopted a fad for drinking large amounts of water, and they may experience relief in a very few days on the modification of this habit.

The explanation for these headaches as well as those due to more definite pathological causes, may be found in the mode of resorption of cerebrospinal fluid. In the publication of the Association for Research in Nervous and Mental Diseases concerning the Human Cerebrospinal Fluid, a number of experiments by Weed and Hughson are recorded, which seem to indicate that the fluid is resorbed chiefly by the basilar dural sinuses, but that, after intravenous injection of hypertonic saline, the fluid could be traced through the meninges into the

Cerebral haemorrhages would appear frequently to cause headaches when they are not profuse enough to cause coma or where the patient has regained consciousness, but the frequency with which such patients give a history of headache for a varying time before the occurrence of apoplexy would seem to confirm the suggestion that the blood vessels, especially when diseased, may be the point of origin of many headaches.

It is probable that cerebral haemorrhage also causes headache by increasing the intracranial pressure, and I am persuaded by a series of cases which I have collected, that subdural haemorrhages may cause intense headache fairly well localized and which being instantly relieved by lumbar puncture, would indicate that the tension of the dura mater causes pain, though not necessarily in itself, but possibly in its vessels. In speaking of the relief of headache in brain tumor by decompression I suggested that the sensitive part of the dura mater might be its blood vessels.

Headache is so frequently associated with disease of the accessory sinuses that very close inquiry is here indicated. This is true both of acute and chronic conditions. I would like to emphasize a statement that X-ray examination will not always indicate that local disease in the nose and its accessory sinuses exists to the degree that headache will result and so a negative X-ray should not be used to exclude this possible source of an otherwise suggestive headache.

Headache may be caused by disease of the nasal accessory sinuses by absorption of toxin by accumulation of the mucous secretion in obstructed drainage channels, and this whether the contents be purulent or merely mucous, and by negative pressure in the sinus which may be caused by turgescence of the drainage channels and subsequent absorption of the contained gases.

The increased pressure of retained secretion and the negative pressure in cases of blockage perhaps emphasize best a phenomenon to which I should like to refer again, namely the disproportion between the strength of sensory stimulus and the resulting headache.

Whatever may be our conception of the disturbance of pressure in these sinuses, most particularly the negative pressure sometimes occurring, I think we shall all agree that the headache is surprisingly severe in proportion to such a slight mechanical force, when we consider what a slight degree of pain this force would cause applied elsewhere on the surface of the body. It shows also the diffuseness which I have spoken of as being characteristic of deep pain and visceral pain.

I would emphasize again how little aid X-ray examination may give in these cases. For the

production of severe headache it is not necessary that a very thick pus should accumulate, nor that the lining membrane of the sinus should be much thickened. I have frequently seen patients immediately relieved of headache by a nasal spray or a simple inhalation containing menthol. If these measures are followed by the blowing out of a muco-purulent secretion one feels justified in thinking that this secretion has been responsible for the headache. I would, however, further suggest that two other factors may be concerned. A flushing of the mucous membrane in its depths may relieve it of toxin and also the sedative action of the spray or inhalation may be sufficient to relieve the headache by abolishing or reducing the afferent impulses that prolong and aggravate the headache.

Perhaps I might elaborate at this point what I have suggested about slight afferent impulses causing such great pain in the form of headache. It is necessary to bear in mind that these afferent impulses must probably be continuous, since an interruption of their flow results in an immediate relief from the headache.

Another strikingly simple expedient will give at least temporary relief, but, since it is so simple, it is probably of great importance in understanding headache. I refer to the application of a cool hand to the forehead, or to massage of the scalp and such like popular remedies.

I attempt an explanation of these measures because it may lead to a better understanding of the processes at work and may be an aid to treatment. I give the explanation on my own authority, admitting that I am taking a liberty with one of Head's theories.

He points out that impairment of epicritic or superficial sensibility allows the protopathic or deep sensibility to obtrude itself as discomfort or even pain, and so ascribes to epicritic and superficial sensibility an inhibitory influence over those more primitive sensibilities. I would suggest that, in applying cold, heat, or counter irritation to the surface, we are stimulating the normal superficial sensibility to greater intensity and so again inhibiting a deep sensibility pathologically raised by disease.

One sees at times, either in operation or post mortem, great accumulations of granulation tissue between the dura mater and the cranial bones near the sinuses. These cases are characterized by long continued and severe headache which obstinately resist all forms of treatment.

Their possible existence is to be kept in mind when a case of headache apparently associated with a catarrhal process, proves intractable.

Headache in association with ear trouble is in my experience, practically non-existent. If ear disease should lead to uncomfortable sensations within the head, these are usually de-

## THE DIAGNOSIS OF PERNICIOUS ANEMIA\*

(Based on a Study of 143 Cases)

By JOHN A. LICHTY, M.D., CLIFTON SPRINGS, N. Y.

SO long as the nature of pernicious anemia is not more fully understood than at present, any curative, and especially any preventive measures proposed for this condition will be largely unsatisfactory.

The cause of pernicious anemia is not known. No constant pathology has been recognized. There is even not any agreement on the part of leading clinicians as to the symptom complex which constitutes this so-called disease.

If our present day knowledge of such well established diseases as typhoid fever, or malaria, or syphilis, were reduced to that of our present understanding of pernicious anemia, we would be in a position to appreciate the better our incapacity as to the problems of pernicious anemia. Under these circumstances it seems well that from time to time contributions be made from various standpoints in the hope that a fuller understanding may result.

It is the purpose of this paper to present the clinical aspect of pernicious anemia, especially from a diagnostic standpoint, as it occurred in some 150 consecutive cases as they came and went throughout about 25 years, or from 1897 to 1924.

It might be well to show at once in what order these cases occurred and what the outcome was. The division of cases is rather arbitrary—

TABLE I—Incidence

Period	Number	Living	No Rec- port	Dead
I (1897-1911)	37	1 (since 1905)	0	36
II (1912-1917)	36	0	7	29
III (1918-1924)	70	2	9	59
Total	143	3	16	124

In the first period of fourteen years spent in general practice 37 cases were observed, an average of 2.6 per year. In the second period covering five years of hospital and consultation practice 36 cases were seen, an average of 7.2 cases per year, while in the third period between 1918 and 1924, six years, 70 cases came under observation, an average of almost 12 per year. It will be noted that the third period covered a time when on account of the war and concomitant circumstances people were under great stress and strain. This period also happens to be that of *blood transfusion* as a more or less routine treatment. It is worthy of note that from 1911 to 1923 the number of new patients of all kinds seen each year varied very little. It is evi-

dent that the incidence of pernicious anemia in the third or last period was about twice that of the second period, though the number of new patients of all sorts remained about the same.

TABLE II—Analysis

Cases of Pernicious Anemia	Males	Females
Age (years)	75	68
Average	50	55
Males	55	41
Females	41	2
Youngest (female)	2	79
Oldest (male)	79	
Occupation		
Out-door work (including 4 coal miners)	30	
In-door work	113	

The criteria upon which these cases were diagnosed varied very little in the 25 years during which they occurred. About the only advancement towards efficiency in diagnosis which seemed to have been made was that on account of a greater interest in pernicious anemia on the part of both physician and laymen the diagnosis was made more promptly and with greater assurance as time went on.

## SYMPTOMATOLOGY

The leading symptoms were presented by the patients in about the following order:

TABLE III—Symptoms and Signs

Prodromal—	Shortest	2 years
First noticed—	Longest	20 years
Weakness	55	
Digestive	55	
Nervous	14	
Circulatory	9	
Characteristic skin	63	
Diarrhea	63	
Parasthesia	58	
Cord Symptoms	40	
Teeth	64	
Glossitis	94	
Enlarged Spleen	19	
Biliary System	10	
Remissions	68	

1. *Weakness*, more or less general, but more frequently referred to the knees. It was unexpected to the patient and no satisfactory explanation could be given. It remained a part of the disease picture practically throughout the entire course, 55 patients noticed this as their earliest symptom.

2. *Disturbances of Digestive System*, such

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 10, 1927.

perivascular spaces and into the ependymal lining of the ventricles, and it is further suggested that changes in the concentration of the blood occurring more naturally may influence the resorption of the fluid. It has not, of course, been proved that these disturbances cause headache, but it is a fairly safe assumption, and when we are dealing with such substances as are retained in nephritis, it is not hard to picture, in addition to any gross mechanical disturbances, the finer osmotic influences as well as the direct intoxication of the sensitive parts.

Menigitis would obviously disturb resorption, and even a severe rhinitis or sinusitis might well be accompanied by a congestion or stasis in the most important locus of resorption, usually the cavernous sinus.

How frequently a headache is accompanied by a feeling of heat in the face and head, and how a depletion of the body fluids by diuresis or more particularly purgation relieves headache, is a matter of common knowledge, and suggests disturbances of resorption by congestion.

I hardly like to touch on migraine for the reason that I have little confidence in what I might say about it.

I would emphasize, and at the same time limit the functional part of it. Migraine has a great tendency to be familial in its occurrence, and this strong factor of suggestion in a household may well account for some cases among the more neurotic members. Nevertheless migraine is not confined to the neurotic, and some of the manifestations in the more severe forms convince us that a very real disturbance takes place. I refer to the transient hemianopia that some patients report, and which can be mapped out accurately with a perimeter. This would place the disturbance posterior to the optic chiasm, and when we see, in the same or other patients, transient aphasia, we are almost compelled to think of a vascular lesion over the cortex.

The frequency with which attacks of migraine pass off with an attack of vomiting directs our attention to the gastro-intestinal tract, and perhaps in particular to the stomach, and many cases of improvement are reported from alteration in diet and intestinal antiseptics.

Adopting this theory of origin in preference to the idea that the vomiting might be of central origin, would be consistent with what I have discussed under the head of chemical dis-

turbances, or the condition might be due to local spasm or dilation of vessels from toxin acting locally. But again, and because the diagnosis of migraine is sometimes made too readily, I would refer to my remarks on local intoxication from nasal conditions, and also on abnormal afferent impulses from the nose and from the eye, and ask for a most complete examination before accepting this diagnosis.

I have said very little on actual diagnosis in any particular type of case. My position here today renders me diffident about doing so, when my paper is to be honored by discussion under various specialists. I do suggest, however, a few simple rules which may add significance to a carefully taken history.

It may be noted that I have discussed almost entirely chronic or habitual headache. Those of acute onset are not likely to be of such importance or their origin will probably be more obvious than headaches whose origin has been lost in a multitude of illness, or which have come on insidiously. I am in the habit of asking of patients where their headaches are, how often they occur, how long they persist, what seems to produce them and what the patient has found for himself will aggravate them or relieve them.

Most important of all, is the question as to whether they wake the patient at night or keep him from going to sleep. These cases should always demand a careful investigation into the possible existence of three diseases, brain tumor, nephritis and syphilis.

I would suggest that headaches coming on frequently and with suddenness are very significant of sinus trouble.

Obviously, when reading seems to bring on headache, we are inclined to think of eye strain, and yet how often in the realms of neurology and psychiatry we find pain in the eyes and photophobia where no eye strain or other abnormality of the eyes can be discovered. I do not wish to underate the importance of eye strain, but merely to urge an open mind.

Of what value this paper may be I cannot say. Certainly it is incomplete, and the problem is far from solved. Many disappointments have demonstrated this to all of us. My object has been to intimate a minimal knowledge of possibilities that practitioners should possess whether in general practice or in a specialty, so that we may not hear men, from their individual point of view, stating that this or that condition is the commonest cause of headache.

have suggested various indirect methods of demonstrating achlorhydria where gastric analyses cannot be obtained. Dr Hubbard, working in our laboratory has made an original investigation of one of these, the change in reaction of urine known as the alkaline tide, and has shown it to be of value in clinical studies. The use of this method in cases where gastric analyses cannot be obtained gives information about the probable presence or absence of hydrochloric acid in the stomach. This determination is of value not only in making the diagnosis but also in establishing a helpful treatment for pernicious anemia. The question is occasionally propounded as to whether the achylia is primary or secondary in these cases. A number of my cases of achylia with normal blood picture were kept under observation, the longest for a period of twelve years, before the symptoms of a pernicious anemia appeared, (this later proved fatal.) Another question occasionally propounded is whether the patient with an achylia in health, and later suffering from pernicious anemia, ever had a normal free HCl in the stomach.

In 1906 I saw a male patient, aged 51 years, who had symptoms of peptic ulcer. His gastric contents were Free  $\text{HCl}_{31}$  combined  $\text{HCl}_{10}$ , and a total of 73. His blood showed a secondary anemia at all times. After a year's treatment he seemed well. In January 1921, or 15 years after the peptic ulcer symptoms, he returned to the hospital following an ethmoiditis. He was pale and had progressive gastric symptoms. An achylia was found. The seriousness of the condition seemed to warrant an exploratory laparotomy. Later the blood picture of pernicious anemia was recognized. In June 1921, the patient died. The autopsy revealed the characteristic negative findings of pernicious anemia.

3 Another laboratory examination is that of the feces. This is largely for intestinal parasites, and for traces of blood. An interpretation of the positive findings may lead to the diagnosis.

4 An X-ray Examination of the gastro-intestinal tract should be done in all suspected cases for at least two reasons. It is not well to interpret a case of achylia gastrica without searching for other conditions such as carcinoma somewhere in the digestive tract or elsewhere, a condition usually associated with the absence of free HCl.

#### GENERAL CONSIDERATION

With a history describing such symptoms and signs, and with such corroborative laboratory results, the diagnosis of pernicious anemia may be made. But to the experienced and careful clinician it will necessarily always remain a tentative diagnosis until the patient dies, or until the post mortem findings are available.

The reason for this is of course that there is no pathognomonic sign or symptom, and there are

certain conditions or diseases which at times so clearly suggest pernicious anemia. Among these are

TABLE V—*Diseases Suggestive of Pernicious Anemia*

- 1 Achylia Gastrica
- 2 Tropical Sprue
- 3 Fish Tape Worm Anemia
- 4 Carcinoma of Gastro-intestinal Tract
- 5 Early Addison's Disease
- 6 Other Primary Anemias
- 7 Certain Secondary Anemias due to
  - (a) Hemorrhoids
  - (b) Uterine Fibroids
  - (c) Nephritis
  - (d) Arteriosclerosis

1 *Achylia Gastrica*, already mentioned. I am in touch with a patient now for over thirty years who has an achylia but the blood picture of pernicious anemia is not yet evident. She is 58 years old. There are certain persistent symptoms which are quite suggestive. Time only can tell definitely what will happen.

2 *Tropical Sprue*. In the abstract the differentiation seems easy, but in the concrete individual patient, the case seems at one time to be one condition, and the next, the other. Of the patients suffering from sprue coming under my observation the outstanding difference distinguishing it from pernicious anemia was the persistence of the diarrhoea and the early and persistent low weight. The finding of monilia is considered by many a confirming factor.

3 Carcinoma of the gastro-intestinal tract, or most anywhere that the neoplasm cannot be palpated, or located by an x-ray examination.

4 Addison's Disease, in the early stage, or before the bronzing of the skin is definitely recognized, is quite confusing.

5 Aside from these diseases there are certain conditions characterized by a mild anemia which form a group usually reviewed when pernicious anemia is suspected. These are chronic nephritis, incipient tuberculosis, angina pectoris and general arteriosclerosis.

6 And finally there are the various diseases included under the class of primary anemias, such as splenic anemia, the leukemias and others which in their various stages may present a confusing blood picture. In recent years, or since the nerve lesion and certain nervous phenomena occasionally associated with pernicious anemia have been called to our attention, it seems to be increasingly difficult to interpret certain early manifestations of the disease. These are tingling of the hands and feet and disturbance of the knee reflexes.

It is always interesting in the individual case to speculate on the etiology. The patient usually has an opinion to offer when it is requested, and

as heaviness after meals, periodic loss of appetite, burning of the tongue, and a tendency to looseness of the bowels, especially early in the morning or immediately after meals 55 patients gave this as the first symptom 94 had from time to time a glossitis

3 *Disturbances of Nervous System* Fourteen patients spoke of early nervous symptoms which they could not well describe In some they were like a posterior sclerosis Forty in all had symptoms suggestive of tabes dorsalis, and fifty-eight others had numbness of hands or feet, or both

4 *Palpitation* A few, nine in all, spoke of a heart consciousness, or a throbbing of the vessels of the neck which was annoying A few had occasional nose bleed

5 *"Liver trouble"* Ten complained of their complexion, and thought they were jaundiced on account of a supposed liver or biliary tract disease, which they described rather accurately and convincingly

Among the other symptoms and signs which were noted in a large number of patients were

6 The characteristic lemon yellow color of the skin 63 were noted No doubt all had this at one time or another

7 *Carious teeth* This was found in 64 patients

8 *Enlarged spleen* In 19 patients this was found In as much as the spleen was palpated at one time and again not palpated, it is likely that there were more than 19 patients with enlarged spleen, only they did not happen to be examined when the spleen protruded from beneath the costal margin

9 *Remission* These are most disturbing phenomena of pernicious anemia, probably more so to the physician than to the patient It is on account of these that it is difficult to tell when a case of pernicious anemia really begins In one of the patients of this series it appeared that the case was rather acute, but upon considering the patient's own account of former illnesses it seemed justifiable to conclude that the same condition had existed twenty years previously It is of course the experience of most of those who have followed these cases that a long interval may occur without any symptoms My own experience with these patients is that a searching examination of the blood, done routinely on the apparently cured patient will after all reveal a suspicion of the disease

10 *Maintenance of weight* This is spoken of as being characteristic and it is a fact that the disease may continue for a long time without any loss of weight In the immediately fatal cases, however, the weight will go down In reporting 110 of my cases eight or ten years ago, there was no loss of weight noted in 29 cases, in 6 it was under 10 lbs, in 33 it was between 10-20 lbs and in 14 between 20-30 lbs

11 *Oedema* of feet appears as the anemia progresses, and

12 *A low grade of temperature* develops as a terminal phenomenon It frequently is very high just before death

Such a group of symptoms constitutes a disease picture which is of itself suggestive, but only so

#### LABORATORY TESTS

The laboratory tests necessary to arrive at a diagnosis are none of them sufficient in themselves, but some are highly corroborative

TABLE IV—*Laboratory Tests*

1	Blood	
(a)	High Color Index	119
(b)	Leukopenia	112
(c)	Nucleated Reds	38
(d)	Poikilocytes	143
(e)	Macrocytes and Microcytes	143
(f)	Corpuscular Volume Increase	
(g)	Macht's Toxic Substance	
(h)	High-Icteric Index	
2	Gastric Contents—Achyilia	143
3	Stool Test	
(a)	For Parasites	
(b)	For Blood	
4	X-ray—To exclude neoplasms, etc	

1 Examination of the blood is of first importance A high color index, associated with a leukopenia and with occasional nucleated red corpuscles is the strongest evidence of pernicious anemia With this blood picture there goes also the irregularity in shape and size of the red corpuscles which was found in all cases, exact measurement of these corpuscles has given prognostic as well as diagnostic information The determination of the color index of the blood, which is usually above the normal in pernicious anemia, and the estimation of the toxic substance of the blood according to Macht's method are confirmatory

In the series of 143 cases presented, 119 had a color index above one, 112 had a leukopenia at the time the diagnosis was made, and in only 38 were nucleated erythrocytes found Repeated blood examinations should be made in doubtful cases Also a Wassermann test and a blood culture should be done The Wassermann test was of course not available in the beginning of this series but later two patients showed a positive reaction It was interpreted as a coincidence

2 *Examination of the gastric contents* is to my mind of the utmost importance In my earlier work I found it impractical, and at times impossible to do a gastric analysis in all cases but of the 102 or 106 in which it has been done there was an achyilia gastrica At present I would refuse to make a diagnosis of pernicious anemia in a patient who has a trace of free hydrochloric acid in the stomach content

Studies of the acid base balance of the body

## THE SELECTIVE TREATMENT OF FIBROMYOMA OF THE UTERUS\*

By JAMES A. CORSCADEN, M.D., NEW YORK, N. Y.

**E**FFICIENT management of fibromyoma, or more strictly, myoma of the uterus is of great importance to the community because of the frequency of disease, the increasing economic importance of womankind, the great variety of methods of treatment available, and the diversity of the factors which demand consideration.

Fibromyoma of the uterus is a new growth arising in the myometrium, composed, in the pure type, of interlacing bundles of smooth muscle tissue supported by fibrillary connective tissue strands. The smooth muscle resembles intimately that of the myometrium except that there is greater variation in the size and shape of the cells. The supporting fibrillary connective tissue seldom presents a picture that would suggest a diagnosis of fibroma. This distinction is important because fibroma in other parts of the body changes with considerable frequency into fibrosarcoma and sarcoma, and may become a metastasizing malignant tumor, while myosarcoma developing in a fibromyoma is a pathological curiosity in the autopsy room.

"Fibroids" were first actively treated by the operation of hysteromyomectomy, usually by drawing the entire mass out of the abdomen, transfixing its pedicle, and beneath the transfixing needle throwing around some form of ligature. The mass was then removed and the ligatures allowed to slough off. Death from infection and secondary hemorrhage was so frequent that this maneuver was withheld until bleeding or other symptoms became extreme. About 1860, Hegar, observing the shrinkage of these tumors after the spontaneous cessation of menstruation induced an artificial menopause by removal of the ovaries and observed the same shrinkage. In 1888, Dr. J. Riddle Goffe, now on service at the Woman's Hospital, New York City, was the first to ligate the pedicle on either side by ligatures which transfixed the cervix, remove the uterine mass from the cervix, drop it back into the abdomen, and close the abdomen. In 1894, Baer first ligated the uterine arteries, thus introducing the operation as it is now performed. X-ray was first applied to a myomatous uterus by Freund in 1899, and was introduced through a communication of Albers Schoenberg in 1902. In this same year radium was first applied. By 1909, radiotherapy had become an established method of treatment. This allusion to the historical development of the treatment of the myoma is made to point out that the methods of treatment now in vogue origi-

inated within a comparatively short space of time and that the frequent statements that radiotherapy is more or less new or experimental are due to the local unavailability of and unfamiliarity with these agents rather than to actual novelty or recentness of their employment.

At the present time, then, we have seven distinct types of procedure which are applicable to varying conditions when their variations are considered there appear eleven distinct methods, each indicated for some particular combination of circumstances.

The application of these methods follows along three lines of thought—the management of symptoms, a consideration of lesions present at the time or likely to develop, and, thirdly, of the injurious effects of the procedure employed. The proper management of a fibromyoma of the uterus depends upon the selection of one or more of these eleven methods for application to the particular indications obtaining in the individual. There can be no broad generalizations. This paper is the expression of a viewpoint which has developed from a study of 740 cases of fibromyoma of the uterus in a clinic where the operative and radiotherapeutic facilities and the experience of the personnel are such as to minimize any attitude of favoritism toward one method or the other.

Of the methods indicated in Table I, the conservative management of fibromyomata was almost universal up to the latter part of the last century and was justified by the small number of disasters which attended this procedure. Even with our modern methods of active treatment it is employed in by far the majority of cases, mostly, it is true, because the masses are not discovered, but also where the tumor is small, without symptoms, or causing only slight menorrhagia or dysmenorrhea. Intelligent hygiene with considerable liver in the diet, and specific therapy such as salvarsan for syphilis, will in a fair proportion of cases give good results when these are the only symptoms. When pain, tenderness, or rapid growth indicate degeneration, inflammation or other change this method becomes more and more neglectful. The consequences must be carefully weighed against the harmful effects directly caused by the other more active methods.

Curettage will have no effect on a fibromyoma, but will establish the absence of a carcinoma, and by removing polyps and other intrauterine pathology, stop bleeding and thereby improve the general condition. Also a small number of cases will be relieved of their dysmenorrhea.

More have spoken of over-work and nervous strain than those of having other conditions, and it usually appeared plausible

#### COMMENTS AND TREATMENT

TABLE VII—*Treatment and Results*

Hydrochloric Acid	143
Hygienic and Dietetic	143
Transfusions	45
Colon Lavage	(?)
High Protein	(?)
Record of Death	91
Autopsies	5
Living	3+

In reviewing the results with the various treatments for pernicious anemia which have been attempted throughout the past thirty years, one is impressed with the absolute failure of all treatments. The most promising of these treatments was blood transfusion and yet according to the statistics of many, including my own, the mortality has remained the same. It must be said for this treatment, however, that it has been of great worth in the acute exacerbations, where death seemed imminent. Transfusion in these cases seemed for the time to snatch the patient from the grave. My own experience leads me to conclude, however, that the patient was usually left with a certain lack of resistance which

only hurried on the next acute exacerbation, and that in the end life was probably not prolonged. At one time about a decade ago when transfusion for pernicious anemia was accepted with the greatest favor, a report from Johns Hopkins Hospital gave the following results in 363 cases. Of 31 patients transfused, 6, or 19% had died, and of 332 patients not transferred, 52, or 15.5% had died. These figures are of very little significance when one realizes that at the present time probably all, whether they had been transfused or not, are dead, and also when one realizes that of those who may happen to be living, the diagnosis may be justly questioned.

The present treatment for pernicious anemia, —the high animal proteid or "liver treatment," —has made a profound impression upon the medical profession, as well as upon the laity.

Probably no other treatment has yet been suggested which has afforded the simplicity in application, and the immediate more or less encouraging results which this treatment promises. It is too early even to predict what the outcome of this treatment will be. In the Clinic at Clifton Springs the results have been rather promising, but nothing more definite can be said than this at present. Reports are coming in and statistics are already available. It is our impression from these early reports that in the enthusiasm many doubtful cases of pernicious anemia, that is, anemias of all sorts, may be included in the statistics. Hence the necessity for more careful clinical study. Also that some of the already accepted measures for the treatment of this baffling condition, such as intensive hydrochloric acid medication and frequent transfusions will be discarded in cases where such measures may be helpful in prolonging life. There is no reason why the liver fed patient should not also take hydrochloric acid continuously, and also have a transfusion when a crisis occurs.

## THE SELECTIVE TREATMENT OF FIBROMYOMA OF THE UTERUS\*

By JAMES A CORSCADEN, M D, NEW YORK, N Y

**E**FFICIENT management of fibromyoma, or more strictly, myoma of the uterus is of great importance to the community because of the frequency of disease, the increasing economic importance of womankind, the great variety of methods of treatment available, and the diversity of the factors which demand consideration

Fibromyoma of the uterus is a new growth arising in the myometrium, composed, in the pure type, of interlacing bundles of smooth muscle tissue supported by fibrillary connective tissue strands. The smooth muscle resembles intimately that of the myometrium except that there is greater variation in the size and shape of the cells. The supporting fibrillary connective tissue seldom presents a picture that would suggest a diagnosis of fibroma. This distinction is important because fibroma in other parts of the body changes with considerable frequency into fibrosarcoma and sarcoma, and may become a metastasizing malignant tumor, while myosarcoma developing in a fibromyoma is a pathological curiosity in the autopsy room.

"Fibroids" were first actively treated by the operation of hysteromyomectomy, usually by drawing the entire mass out of the abdomen, transfixing its pedicle, and beneath the transfixing needle throwing around some form of ligature. The mass was then removed and the ligatures allowed to slough off. Death from infection and secondary hemorrhage was so frequent that this maneuver was withheld until bleeding or other symptoms became extreme. About 1860, Hegar, observing the shrinkage of these tumors after the spontaneous cessation of menstruation induced an artificial menopause by removal of the ovaries and observed the same shrinkage. In 1888 Dr J Riddle Goffe, now on service at the Woman's Hospital, New York City, was the first to ligate the pedicle on either side by ligatures which transfixed the cervix, remove the uterine mass from the cervix, drop it back into the abdomen, and close the abdomen. In 1894, Baer first ligated the uterine arteries, thus introducing the operation as it is now performed. X-ray was first applied to a myomatous uterus by Freund in 1899, and was introduced through a communication of Albers Schoenberg in 1902. In this same year radium was first applied. By 1909, radiotherapy had become an established method of treatment. This allusion to the historical development of the treatment of the myoma is made to point out that the methods of treatment now in vogue orig-

inated within a comparatively short space of time and that the frequent statements that radiotherapy is more or less new or experimental are due to the local unavailability of and unfamiliarity with these agents rather than to actual novelty or recentness of their employment.

At the present time, then, we have seven distinct types of procedure which are applicable to varying conditions when their variations are considered there appear eleven distinct methods, each indicated for some particular combination of circumstances.

The application of these methods follows along three lines of thought—the management of symptoms, a consideration of lesions present at the time or likely to develop, and, thirdly of the injurious effects of the procedure employed. The proper management of a fibromyoma of the uterus depends upon the selection of one or more of these eleven methods for application to the particular indications obtaining in the individual. There can be no broad generalizations. This paper is the expression of a viewpoint which has developed from a study of 740 cases of fibromyoma of the uterus in a clinic where the operative and radiotherapeutic facilities and the experience of the personnel are such as to minimize any attitude of favoritism toward one method or the other.

Of the methods indicated in Table I, the conservative management of fibromyomata was almost universal up to the latter part of the last century and was justified by the small number of disasters which attended this procedure. Even with our modern methods of active treatment it is employed in by far the majority of cases, mostly, it is true, because the masses are not discovered, but also where the tumor is small, without symptoms, or causing only slight menorrhagia or dysmenorrhea. Intelligent hygiene with considerable liver in the diet, and specific therapy such as salvarsan for syphilis, will in a fair proportion of cases give good results when these are the only symptoms. When pain, tenderness, or rapid growth indicate degeneration, inflammation or other change this method becomes more and more neglectful. The consequences must be carefully weighed against the harmful effects directly caused by the other more active methods.

Curettage will have no effect on a fibromyoma, but will establish the absence of a carcinoma, and by removing polyps and other intrauterine pathology, stop bleeding and thereby improve the general condition. Also a small number of cases will be relieved of their dysmenorrhea.

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y May 10 1927

Myomectomy should be reserved for those women who desire children. As a cure for sterility, it gives a prognosis of about ten per cent. The scar in the uterus will only be a slight handicap in her labor. As a cure of bleeding, except where the myoma is polypoid, for improving the general condition, and the elimination of other symptoms, myomectomy has not proven efficient. Amongst the group of cases who have required radiotherapy for uterine hemorrhage, there are twelve who have had a previous myomectomy or partial hysterectomy. In some of these new myomata had developed, in others the bleeding had evidently been functional in character, the tumor merely coincident. The mortality and morbidity is higher but the discomforts from the menopause less than those following hysterectomy.

Supravaginal hysterectomy is the method most frequently employed for the relief of symptoms and removal of diseased tissue. Because it eliminates the endometrium, it will stop all bleeding whether due to the tumor or not, and will relieve most cases of dysmenorrhea except those of ovarian origin which may continue as periodic pains although menstruation has ceased. It is better than radiotherapy for the elimination of pain occurring at times other than at the menstrual period, but should not be given too perfect a prognosis because pain in the abdomen associated with fibromyoma is often due to conditions outside of the uterus. Cases of carcinoma of the ovary and sigmoid, cholecystitis, gastric ulcer, pyonephrosis, and numerous cases of adnexal disease have been referred for treatment of the uterine condition because this was so obvious and the true condition so obscure. Pain with fibromyoma of the uterus demands a very careful diagnosis, as do the urinary symptoms. Relaxation of the pelvic floor, trigonitis, and tuberculous kidney have been the causes of urinary disturbance in women referred for management of their uterine tumors. In the case of the tuberculous kidney, I refused to do a hysterectomy through four cystoscopies. Pus was finally obtained from the left kidney. Symptoms of toxemia (anemia without bleeding to account for it) and malaise are infrequent but occasionally important, and have been relieved by hysterectomy. In these cases there was a cystic or red degeneration. Heart disease or hypertension have not been improved, although the late Dr. Studdiford cites a case in which this was accomplished.

One of the most important phases of an abdominal hysterectomy is the opportunity for an exploratory celiotomy and the elimination not only of the uterine mass but possibly of other coincident disease. While this should not be used as a screen to cover up superficial

diagnostic methods, it is one of the most important considerations, particularly in multilobular masses where one of the lobes is often found to be an important ovarian tumor. Where edema and congestion indicate pressure from the mass, its removal is indicated. One such case was treated by radiotherapy because of the precarious condition of the patient. While hemorrhage ceased and her general health improved, the relief from the pressure was so slight that hysterectomy was performed as soon as her condition would warrant it. The mortality and postoperative course following hysterectomy is so well known that it need not be discussed here except to stress a point learned in the follow-up clinic—that convalescence, rapid for the first few weeks, is slow after the second month, and patients should be instructed to regard themselves as in need of varying degrees of care for a period of at least six months.

Up to this point supravaginal and complete hysterectomy may be regarded as giving the same results. The incidence of carcinoma of the cervix in stumps left in after supravaginal hysterectomy is frequent enough to demand attention and must be balanced against the increased technical difficulties and greater operative mortality and morbidity of the complete operation. If the cervix is diseased, it should be removed; if not, it should be managed as if there were no fibromyoma present. Prophylactic excision should be performed for cause and not routinely.

The question of the removal of the ovaries is still open. The conventional attitude is to leave them in. A few, as Dr. Graves of Boston, believe that the immediate disturbances from dysfunction and the high incidence of subsequent degenerative changes in the ovary demand their routine removal. The follow-up examination of the cases in this clinic seems to show that menopause symptoms are less severe and of more gradual onset where the ovaries were left in. At the same time the number of ovarian cysts which have developed in these cases is large enough to receive serious consideration. It is the practice, therefore, to remove the ovaries routinely in women over forty years of age and those in women below that age in which there are any important cystic changes at the time of operation.

Simple ovariectomy is seldom performed nowadays. I have done it in three cases of large myomata with massive vascular adhesions between the tumor and the intestines. In two of them the mass receded slowly with partial relief of pain and urinary distress which had indicated the operation. In the other, menstruation continued, evidently because some ovarian fragments had been left in treated by X-ray the mass subsided with com-

plete relief of symptoms. This procedure should be reserved for such complicated cases where prolonged and difficult dissection would endanger the patient's life. With the numerous methods of treating myomata at our disposal, a mortality from elaborate dangerous operative procedures seems unjustifiable.

Radiotherapy by radium or x-ray is the most frequent alternative to excision for fibromyoma. It may be given in doses which will stop menstruation and precipitate hot flashes characteristic of the menopause, in doses calculated to modify but not destroy menstruation, or again may be applied directly to the uterine mass in such a way as to avoid direct exposure of the ovaries. Specimens of uteri and ovaries following radiotherapy are not numerous. This speaks well for the method but deprives us of any large amount of material for study. We depend, therefore, upon our follow-up examination of the patient to determine what the anatomical and physiological effects have been. A sterilizing dose of radium or x-ray has stopped bleeding from all uteri where there has been no ulcerative process. Apparently, active or passive congestion are not sufficient to initiate bleeding where the menstrual stimulus is absent. If the bleeding comes from an exposed ulcerating surface like that of a pedunculated intrauterine mass (in the extreme case presenting in the vagina and obviously subject to trauma) the precipitation of the menopause will not stop it. The local caustic and sclerosing effect upon these ulcerating masses of radium inserted into the uterus may stop the bleeding, but the dangers incident to the sloughing process make this procedure much inferior to simple excision either of the intrauterine mass or of the uterus. Dysmenorrhea has been almost universally cured. The other symptoms indicated have been much less satisfactorily relieved than by hysterectomy. Here again the importance of the extrauterine causes of the pain, urinary and digestive symptoms must be emphasized. When these symptoms dominate the picture they place a much heavier diagnostic burden upon the radiotherapist than upon the performer of the exploratory celiotomy which should be made unless the symptoms have been satisfactorily explained in the preoperative diagnosis and found to be unrelated to the uterine condition.

The size of the uterine tumor is often the only indication for treatment. There is a fashion in this country to excise all masses larger than that of the size of a three months pregnant uterus. The effectual reduction of the larger masses by radiotherapy is questioned. Table II shows results in one hundred and five cases. Certainly a reduction of a mass the size of an eight-months pregnancy

to one of seven or eight centimeters in diameter with very little interference with the daily activities of the patient is very satisfactory. Nevertheless, the more frequent occurrence of degeneration in large masses, the greater likelihood of diagnostic error, the anxiety of a patient reporting every month or two for measurement of the mass and the slowness with which a disfiguring enlargement of the abdomen disappears impel me to excise the large tumors. At the same time, the patient must be protected against the harmful effects of operation and if even minor contraindications exist should have radiotherapy considered.

The fear of coincident extrauterine pathological lesions has deterred many from using radiotherapy because of the possibility of leaving untreated dangerous conditions such as tumors of the ovary, and on the other hand of lighting up latent inflammation of the adnexa. Unless ovarian tumors can be certainly eliminated, the patient should without doubt have the benefit of an exploratory celiotomy. Two dermoid cysts have been removed, having been referred because X-ray treatment had failed to reduce the size of the supposed myoma. On the other hand, chronic salpingitis without symptoms or physical signs is of less importance and merits the same treatment as it would were there no coincident fibromyoma of the uterus. Amongst my cases there have been four infections following the intrauterine application of radium, two of which went on to abscess formation, every one originating in the uterus, spreading to the broad ligaments, none of them starting primarily in the peritoneal cavity. Moreover, we have deliberately treated with X-ray four women in whom hysterectomy was abandoned because of extensive adhesions with salpingitis, in one case tuberculous, with no evidence that the inflammatory process was lighted up. One woman suffering for two years from a tuberculous fistula following salpingectomy was healed after X-ray therapy. My experience would indicate that the inflammations occurring after radium therapy are for the most part simple operative accidents and not the result of electromagnetic waves upon a latent focus.

Acute degenerations of a fibromyoma following radiotherapy have been infrequently reported in the literature. I have not had this experience and feel that such an accident is likely to occur in those tumors which have already begun to degenerate and should reveal themselves by local signs of inflammation or by symptoms of absorption. The possibility of a coincident carcinoma of the uterus is often mentioned as a reason against using radiotherapy for myoma. To me the two problems

have no connection. Before treating any fibromyoma of the uterus by either excision or radiotherapy, the absence of a carcinoma must be thoroughly established by examination under anesthesia and curettage. An operation designed for the removal of a fibromyoma of the uterus is inadequate for the treatment of a carcinoma.

The possibility of the occurrence of important conditions at a considerable interval after radiotherapy for fibromyoma has been stressed, particularly red and cystic degenerations and sarcomatous change in the tumor mass, and increased likelihood of carcinoma because of persisting chronic irritation. Of my cases none has given evidence of any except possibly hyaline degeneration in the tumor. There is an unconfirmed report that one woman developed carcinoma of the uterus two years after she had had radiotherapy. There has been no case admitted to the Presbyterian Hospital and few cases are reported in the literature of carcinoma of the uterus developing in a woman who had had radiotherapy for fibromyoma. The development of sarcoma in a fibromyoma is to me an academic and not a practical problem. Despite the reports of bizarre microscopic pictures, called sarcoma by many investigators of myomatous tissue, the autopsy rooms still remain as empty of women dead from sarcoma of the uterus as they did in the years before hysterectomy was so universally performed. Dr Stout and I in studying one phase of this problem, could find in the literature only three cases of sarcoma which developed in fibromyomata previously treated by radiotherapy.

The dangers of this method are less than those of any of the operative methods. With a diagnostic curettage, however, there is the ordinary risk of operative accidents, such as embolism and infection, increased by the radium slough in the uterus. There is also some toxemia from any considerable dose of radiotherapy. The radiotherapeutic menopause (Ref.) may cause unpleasant symptoms, but has not produced important changes even in younger women, ten of whom under twenty-five years of age have been followed from nine to thirteen years.

Non-sterilizing doses of radium or X-ray are, like myomectomy, considered almost entirely from the standpoint of future child-bearing. For the relief of symptoms, especially bleeding, they are unsatisfactory because of the varying susceptibility of the patients. Compared with the operation of

myomectomy the results on sterility and in the relief of symptoms have been inferior to the operative method. When the uterus is studded with small masses, making myomectomy impractical, the partial dose may have a field. Comparing radium and X-ray, the former may be given at the same time as a diagnostic curettage which is in fact, always indicated, it produces in the long run not very much more discomfort than do X-ray treatments, and from the standpoint of convenience is less distressing to most women because it is incidental and finished with one application. Against the use of radium is the increased danger of infection due to the radium slough. X-ray may be given without interruption of the activities of the woman and avoids hospitalization. With large myomata there is a more rapid effect on the tumor by X-ray and greater certainty of producing the menopause because of the possibility of the ovary being lifted away from the uterine cavity, and consequently at a distance which makes the radium ineffectual.

#### Conclusions

(1) The frequency of fibromyoma of the uterus, the great variety of available methods, and the diversity of the indications for treatment demand a careful selection of method.

(2) Expectant treatment is the method of choice in small symptomless tumors.

(3) Curettage will exclude carcinoma, cure bleeding due to certain intrauterine causes, and relieve dysmenorrhea.

(4) Myomectomy is reserved for women desiring children. Supravaginal hysterectomy is employed whenever the tumor becomes a menace to the patient as revealed by signs of inflammation, degeneration and rapid growth, and for bleeding from ulcerated surfaces. Complete hysterectomy is employed when the cervix would demand excision irrespective of the fibromyoma.

(5) Simple oophorectomy is performed in complicated cases where the completed operation would endanger the life of the patient.

(6) Sterilizing doses of radiotherapy are indicated for hemorrhage not due to ulceration, and for all other indications where hysterectomy is contraindicated. Non-sterilizing doses of radium or X-ray are employed only when child-bearing is desired and where myomectomy is impractical.

POINTS OF CONTACT BETWEEN DERMATOLOGY AND OTHER BRANCHES  
OF MEDICINE\*

By CHARLES M WILLIAMS, M D, NEW YORK, N Y

THE careful dermatologist has recognized for many years that if he is to get the best results in his practice, he must look upon a dermatosis as a symptom rather than a disease. It may be the most important symptom, and the disease may be confined to the skin and its appendages, but on the other hand the dermatosis may depend on a general infection, or on lesions in distant parts of the body.

There is a very large and as yet ill-defined group of eruptions which depend on focal infection. In the simplest cases of this group, the infection spreads by peripheral extension, or by external inoculation. An excellent example of this is an inflammation of the upper lip caused by infection with germs contained in the nasal discharge. The dermatitis may be very mild, appearing as redness and slight swelling, with itching, or it may be very severe, with much swelling and many pustules, or it may be anywhere in between. The severe cases are classed as sycosis of the upper lip, a region which is seldom, if ever, attacked by ringworm organisms. Treatment directed to the lip alone is usually without avail—the nasal condition must be treated also, and the source of infection must be sought throughout the nasal tract, including the accessory sinuses. A similar eruption may be dependent on a discharge from the ear. This is seen less frequently, as otitis media is less frequent than chronic nasal catarrh. It is commonest in these two groups to see the inflammation spreading directly from the nostril or the auditory meatus, but in some cases the infection is carried by some agent, as the hand, to a point removed from the primary focus, where it sets up an inflammation which may take the form of folliculitis, cutaneous abscesses, boils, or acute eczematoid dermatitis.

To this same group belong the cases of tuberculosis of the skin occurring on the buttocks, nearly all of which are due to infection with organisms discharged at the anus.

There is probably another element in the etiology of all these cases besides local inoculation of pathogenic organisms. We are familiar with the superficial crust of impetigo, which is simply a mass of dried pus and epithelial debris, and with the pustules of various sizes which are produced by staphylococci, and in both these instances the inflammatory reaction is strictly limited. In many of the cases which I have in mind, however, the reaction is not so well defined, there are crusts and

pustules, to be sure, but there is also a variable amount of diffuse redness and swelling, an inflammation which is irregular, with no sharp borders, and which seems to involve the entire thickness of the skin over a considerable area. This is not the ordinary reaction of the skin to a virulent organism and I believe that the skin of these patients has been sensitized by toxins which have been absorbed from the primary focus.

The two particularly striking instances of this infectious dermatitis secondary to a local infection have come to my notice. One occurred in a group of young children varying from a year and a half to six years of age. All were in the children's ward of the New York Skin and Cancer Hospital, under treatment for eczema, so we may assume that their skins were abnormally sensitive. One of these children was subject to repeated attacks of coryza, with a profuse muco-purulent nasal discharge. If he was allowed to play with the other children while his nose was running, each had an exacerbation of his eczema, and treatment was unsatisfactory until the offender was isolated or his coryza relieved. The second instance was that of a girl with recurrent attacks of eczema, involving chiefly the face, but occurring on other parts of the body also, especially under the breasts. Treatment was unsatisfactory, the attacks occasionally yielding, for a time, but always recurring, with no apparent cause. She had occasionally a slight discharge from one ear, but she complained of no symptoms referable to the ear, and when first admitted to the hospital, there was no discharge. After a radical mastoid operation, the eczema disappeared.

An eruption of this genesis, when it can be recognized, should be taken out of the waste basket labelled eczema, and put in its proper pigeon hole of parasitic dermatitis. Whether anything will be left in the waste basket, still to be called eczema, after the removal of these cases, and of those cases of dermatitis caused by physical or chemical irritants acting from without, is a question as yet unsolved.

In addition to this spread of infection by external inoculation, hidden foci affect the organism in other ways which are perhaps even more important to the dermatologist, as they certainly are to the general practitioner. We are all familiar with the idea that rheumatism, endocarditis, and probably many other diseases, are caused by absorption from foci of infection of bacteria and of toxins which find lodgement in distant organs. It is now proved of many skin diseases, and suspected

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls N Y May 10 1927

of others, that they have a similar etiology. Notable among these are the whole group of the erythemata, from urticaria on the one hand, to purpura on the other. These so-called diseases should be considered as symptoms, not as separate entities, for two reasons: first, because there are many border-line forms which are hard to place, and second, because each may spring from any one of several causes. Urticaria, as its name implies, is the wheal which is caused by contact with the nettle. Other external irritants, such as the jelly-fish, cause an identical eruption. These cases of external origin are rarely seen in city practice, where "hives" are commonly a symptom of the absorption of toxic material from the gastro-intestinal tract, the toxic material being a food-stuff to which the patient is sensitive, or some product of decomposition. Others, especially those characterized by prolonged and repeated attacks, seem to have no relation to the intestinal tract. The etiology of these cases is most obscure. Some are probably due to endocrine disorder—they certainly are relieved by adrenalin—and some are probably due to toxic absorption from a bacterial focus. Cases have been reported as due to syphilis. Closely allied to urticaria is angioneurotic edema, which differs from ordinary hives in that the swelling is much greater, though less firm, in the absence of pruritus, and in the fact that it can seldom be associated with errors of diet. The swelling appears suddenly, lasts a short time, seldom more than a few hours, and disappears about as suddenly as it came. It is best explained as a disorder of the vaso-motor mechanism, but that only pushes the inquiry one step further. What disturbed the vaso-motor mechanism? A circulating toxin is the most likely explanation. Next above urticaria are the various forms of erythema. A diffuse erythema following the ingestion of a food to which the patient is sensitive is well recognized, as is also a scarlatiniform erythema followed by peeling, which is caused by toxic absorption from the intestines. The eruption called erythema multiforme is more difficult to place. It is probably always toxic in origin, but there remains always the question of why the same toxin will produce this eruption in one patient and not in another. How did he get that way? The most diverse toxins have been incriminated in some cases; drugs in most cases, particular articles of food or products of intestinal decomposition, but there still remains a large class where no such cause of intoxication can be found, and in these it is probable that the toxin is the product of a bacterial focus. The limited duration of the individual attacks, and the tendency to recur, are both consonant with what we know of the variations in susceptibil-

ity and in resistance in the course of a chronic infection. As pointed out by Osler, the lesions of erythema multiforme may occur on any of the mucous membranes, and occurring on the intestinal mucosa, may give rise to a variety of very confusing symptoms.

Closely allied to erythema multiforme is erythema nodosum, characterized by firm red painful swellings, usually situated on the legs, lasting a few weeks, and terminating by absorption, sometimes with preliminary softening. The inflammation in these cases is deeper seated than in erythema multiforme. Exactly the same causes are ascribed to this eruption as to erythema multiforme, with the addition of tuberculosis. There is this difference, however, that whereas erythema multiforme is in many cases believed to be of intestinal origin, erythema nodosum is, in the vast majority of cases, due to a bacterial toxin. In both these forms of erythema, petechial hemorrhages occasionally occur, allying these diseases to purpura.

Erythema induratum, characterized by granulomatous masses in the skin and subcutaneous tissue, occurs most often on the calf of the leg and in young girls. The masses develop very slowly, last indefinitely and may disappear by absorption, usually with superficial ulceration. It is generally considered to be tuberculous in nature, but some of the cases are almost certainly due to other organisms, and some are almost if not quite indistinguishable from erythema nodosum.

These three groups, erythema multiforme, erythema nodosum, erythema induratum form a series, having many points in common, particularly the occurrence of bacterial toxemia as the most important etiological factor. It may be difficult in a given case, to decide whether the lesion should be called erythema nodosum or erythema induratum, but the decision is not an important one. The really important thing is to recognize that the eruption is a symptom of toxemia, that the toxemia is probably bacterial, and that the focus of infection must be looked for. It is doubtful if there is any organism of which it can be said this is the specific parasite of erythema multiforme.

The purpuras are a similar series, varying from petechial spots alone to severe hemorrhages into the skin and through the mucous membranes, with high fever and death. Here again it is important to remember that purpura is a symptom, not a disease. Aside from the cases associated with hemophilia, icterus, leukemia, and other blood defects, it is nearly always a symptom of toxemia, and it may be caused by any one of a large number of organisms.

The diseases so far considered are now

generally classed as toxic. There are others whose etiology is still undetermined, but which tend more and more to fall into the same group. Notable among these is lupus erythematosus, whose etiology has split the dermatological world into two hostile camps—those who believe that it is always tuberculous in origin and those who do not. As is so often the case, careful research is gradually establishing the opinion that neither extreme is justified. Some cases are probably tuberculous, in the sense at least that a focus of tuberculosis elsewhere in the body, by means of toxins which it has poured into the blood stream has so altered the reaction of the skin that it responds in this particular fashion to a local irritation, and the local irritation may in some cases be a tubercle bacillus brought by the blood. Other cases show no sign of tuberculosis, but do show focal infection with other organisms, notably in the teeth and tonsils, while still others, and these are the most serious, seem to be due to a tuberculous infection of the abdominal lymph nodes, combined with a focus of infection with one of the pus producing organisms elsewhere. Some of these latter have been confirmed by autopsy. Lupus erythematosus is a disease of many clinical forms, united by intermediate gradations, and may be caused, apparently, by any one of a number of infections. That it is a toxic eruption is now generally recognized, and many cases respond to the removal of the offending focus.

Alopecia areata is one of the most easily recognized of all skin diseases. The sudden development of areas of absolute baldness, with no disturbance of sensation and no sign of inflammation whatever, cannot be mistaken for anything else. Even without a history, a mistake should rarely be made. During the war, I saw many men who were classed as syphilitic because they had alopecia areata, but I never could discover why the one condition suggested the other, there is really absolutely no connection between the two. I suppose the surgeon, unfamiliar with dermatology, had read that syphilis produces a peculiar type of baldness, and this is certainly a peculiar type of baldness. Therefore, this is syphilis. What could be more logical? And what logic could be more faulty? As a matter of fact, the cause of alopecia areata is unknown. I have seen some cases which improved greatly after treatment of a diseased naso-pharynx, but in others no such infection could be found, and many cases improve with or without treatment. The possibility that this and many other dermatoses may be due to toxemia is fascinating, and opens up a wide field for research. Focal infection suggests at once teeth and tonsils, because these organs

can be examined easily, but what do we know of the chronic infections of the bronchiae and the mesenteric lymph nodes, and how many cases of chronic cholecystitis go unrecognized? Indeed, the temptation to generalize along these lines is so great, that one must be very chary in doing more than offer suggestions.

The skin is one of the most favorable organs for studying the problems of sensitization, and experience gained here is a standing warning against drawing sweeping generalizations from observations on a few diseases. The variations in local reaction of the skin, caused by sensitization, can be learned only by study of each individual disease. No number of observations on the most varied diseases, will enable one to predict what form sensitization will take in the next disease to be studied, it may resemble one of the forms already studied, or it may not. For instance, a patient infected with syphilis is incapable of developing a chancre—his skin will no longer react in that particular way, and yet the spirochaetae will thrive in a mucous patch, and may be recovered from a blister raised over a syphilitic papule. In the course of a year or two, the reaction of the skin changes still further, the generalized rash has disappeared, and it is difficult or impossible to recover spirochaetae from the skin, but spontaneously, or as a result of trauma, the inflammatory masses appear which we call nodules and gummata. Tuberculosis acts in quite a different fashion. General infection does not protect against reinfection, local inoculation may still produce any one of several types of tuberculosis, notably the ulcerative or the warty. In some old cases of tuberculosis, however, the reaction of the skin to haematogenous infection with tubercle bacilli is strikingly similar to the reaction of the skin of a syphilitic to the lodgement and development of spirochaetae. It is notorious that lupus vulgaris and nodular syphilis may present clinical features so similar as to deceive the every elect, and the same is true of erythema induratum and gumma. In these two diseases, therefore, sensitization produces strikingly different results in the early stages, strikingly similar results in the later.

The cutaneous sensitization occurring in kerion and in other cases of severe and deep ring-worm infection are analagous, and yet different. It is made manifest by a generalized eruption, usually follicular, sometimes vesicular, sometimes erythematous, occurring when the original focus has reached or passed its climax, and this eruption may be induced by the injection of a killed culture of trichophyton into a patient with trichophytosis, but not by an identical injection in a healthy subject. The eruption is transitory, and as it disappears there is usually great improvement or even

curt in the original focus of disease. These three diseases, syphilis, tuberculosis and dermatophytosis, are cited for the light which they throw on some of the problems of general medicine. First, each infection is a law unto itself. The response of the body may be similar, in different infections, and results obtained in the investigation of one may be very suggestive in guiding investigations on another, but the facts for each disease must be ascertained by independent observation and experiment, not by reasoning or by analogy. Second, these three diseases all have this in common, that when a patient is infected with one of them, parts of the body far removed from the active focus react differently, at least as far as that particular infection is concerned, from the same parts in a normal subject. Are there similar changes in reaction in the internal organs in general disease? May a severe tonsillitis so sensitize the intestinal mucosa that an enteritis is more easily set up than in a normal subject? How will this sensitization vary with different types of invading organism? How will the sensitized tissue respond to physical injury? The answers can be found only by careful observation and experiment.

When we try to correlate disturbances of the endocrine system with diseases of the skin, we meet such a mixture of fact and fancy, of accurately described observations and illogical deductions, that the task of picking out the data which will serve as a foundation on which to build a working hypothesis is almost impossible. The functions of the thyroid are probably as well understood as those of any of the ductless glands, and estimations of basal metabolism give us a fair estimate of its activity, but aside from myxoedema, cretinism and exophthalmic goiter, in its various forms, we know very little about the effects produced by over action, under action, or perverted action. The skin is thick in myxoedema and the hair is thin, but that is not sufficient reason to conclude that all thick skins and bald heads are the result of deficient thyroid secretion, and I know no way of picking out the patients, except the victims of myxoedema and of cretinism, whose skins are likely to be improved by the administration of thyroid extract. A series of basal metabolism experiments in patients with various skin diseases might teach us something, but I am inclined to believe that though the results obtained would be of help in the treatment of the patient on whom the determination was made, they would probably not serve as a basis for any general system of therapeutics.

The changes observed on removal of the glands have been known for centuries, and similar departures from the normal result from loss of function, whether this be caused by disease

or by lack of development. Changes in the distribution of the hair and of fat are the two features which interest the dermatologist, but we have no convincing evidence that the normal distribution can be restored by gland feeding.

The diseases of the pituitary are becoming increasingly important as knowledge about them increases. Giantism and acromegaly are well defined syndromes, and are almost certainly caused by over secretion by the pars anterior. As there is no known antagonist to this secretion, medical treatment is unavailing. A deficiency in this secretion results in a certain type of dwarfing, without necessary mental change, which may usually be recognized. Another disorder of pituitary secretion, Froehlich's syndrome, is easily recognized in its classical type of short stature, obesity, and delayed sexual development—or if occurring after puberty, in sexual atrophy. Children suffering from this syndrome usually have a narrow maxilla and crowded, often irregular, lower teeth, and the lower incisors are often an eighth of an inch or more behind the upper. In my experience, the upper jaw also is often narrowed, producing a highly arched palate. This condition is to be expected, as it is the direct opposite of what is known to occur in acromegaly. It is impossible to connect any definite skin disease with these changes, but I believe that there is a correlation in children between dryness of the skin, or xeroderma, and narrowing of the jaws, and that these patients are improved by pituitary feeding. Xeroderma is often a predisposing cause of dermatitis, and cases of dermatitis, in patients of this type, often do well under pituitary feeding. I have not sufficient data to offer any proof of this opinion, but the lead is, I think, a promising one.

The tumors of the skin are seen both by dermatologists and by surgeons, and though there is a general agreement as to the general principles of treatment, there is a wide divergence of opinion as to details. Let us consider, for example, the pigmented moles. As a rule, the surgeon has his attention called to these tumors only when they have become malignant and nothing is more malignant than a melanoma. Excision, even when extensive, is usually followed by recurrence. As a consequence, some surgeons seem to advocate the removal of every pigmented mole, before it has become malignant. If this advice were taken literally, what an orgy of operating would ensue. Those of us who had the privilege of examining recruits in the late war, had no trouble in finding three moles on each man, to serve as identification marks—the only problem was to select those most easily described. If every person has three moles, and

there are 120,000,000 people in the United States, what is the percentage of moles that become malignant? It is about as dangerous to leave a mole untreated as it is to cross the street. But all rules have exceptions, and so does this one about leaving moles alone. If, by its size or its location it is subject to irritation, and especially if it shows any response, however slight, to this irritation, it should be removed, preferably by the cold cautery. Senile Keratomata, somewhat similar to some moles in appearance, but of a different nature, can be removed by fulguration, radium or freezing with carbon dioxide snow.

Another point on which the surgeon and the dermatologist are apt to disagree, is on the treatment of cutaneous epithelioma. The opinion of the surgeon, familiar as he is with cancers of the internal organs which occur frequently in late middle life, and which demand early and most radical excision if life is to be spared, is biased by these ideas when he has to consider cancer of the skin. His problem has always been to secure absolute extirpation of the disease at any cost, and in his own field he is justified. But conditions are different in cutaneous malignancy. The tumor, especially if it be of the basal cell type, is relatively slow growing, and usually begins comparatively late in life. In very many cases, therefore, the problem is no longer how to secure absolute extirpation at any cost, but how to give the patient the longest life with the least discomfort. For example, a woman of 83 years came

to my office, with a typical epithelioma, beginning to ulcerate, on the right cheek. It had been observed first fourteen years before, and had then been treated with radium. Seven years later it recurred, and was again treated with radium, with good temporary result but it again recurred. All sign of the disease was removed by a third application of radium. It is probable that she will die of something else before the tumor recurs again, but at the worst, an operation will still be possible if necessary, while at the best, the patient has escaped all disfigurement, and all the danger of a major operation.

This is not a plea for the use of radium in all cases of cutaneous epithelioma. It is a plea for the exercise of most careful judgment in the selection of the mode of treatment to be followed.

And so the list of points of contact might be extended indefinitely, and some of the most important have not been mentioned. The role of the nervous system in the production of lichen simplex, the relation of diabetes to two such diverse dermatoses as xanthoma and furunculus, the effect of circulatory failure on varicose dermatitis—these are but a few of the many conditions that might be discussed. Enough has been said, however, to call attention to the necessity for cooperation between the dermatologist and his brethren in other specialties and in general medicine, if the best service is to be rendered to the patient.

## POST-GRADUATE STUDY

The evidence given at the District Branch meetings has confirmed the opinions of leaders of the Medical Society of the State of New York that one of the great functions of the state organizations is to aid the members of the rural societies in their efforts to learn the modern methods of practice and so bring medical practice to a high level throughout the entire state. Physicians in the larger cities have access to teaching courses and clinics in the hospitals and academies of medicine, and are generous in their offers to aid their medical brethren in less favored districts. Not only are they willing that the major efforts of the State Com-

mittee on Medical Education should be made in the country districts, but they are willing to lend their assistance in giving the lectures and courses. Taking courses of lectures to the rural counties is one of the great public health forces of the state and will go far to solve the question of how to give medical service to those who live in sparsely settled parts of the state. Not more rural doctors are needed, but better ones. The courses will not only impart items of instruction but they will also inspire those who attend them to continue their studies and to attend more extensive courses at every opportunity.

## FUNCTIONS OF MEDICAL SOCIETIES

Physicians one hundred years ago were intensely individualistic—and necessarily so. They were isolated in their communities, and the lack of facilities for travel prevented their association with their medical brethren, and when physicians did get together, the lack of scientific standards prevented their joint action in diagnosis and treatment. A doctor's own experience was the principal basis on which he formed his decisions, and he valued his own practical knowledge above that of most of his colleagues.

The physician of one hundred years ago practiced every form of medicine, and was indeed the general practitioner and family physician to whom his people went for every form of advice along lines of health and hygiene. He was also the advisor of the community in matters of public health, and he ranked with the "Squire" and the pastor in honor among his people. He had great civic pride, and was willing to give the community the advantage of his knowledge of health conditions. He performed the duties which doctors now share with departments of health, and lay organizations.

Medical societies took on renewed activity when railroads afforded them the means of travel, and the progress in medical science gave them standards that were far more reliable than their own narrow experiences. These same two items of progress also led the government to establish departments of health whose officers were expected to give the community that medical advice which the older doctors had given freely, and the doctors welcomed the opportunity to rid themselves of their responsibility for public health.

Philanthropists observed the inability of the poor to avail themselves of medical service, and the growing unwillingness of the physicians to give their advice for nothing, and so they formed lay health organizations in order to bring doctors and poor patients together. From this it was but a step to propose to that the state provide medical advice not only to the poor, but even to all classes of people.

Lay organizations and health departments had much in common, for they were both attempting to do the civic work which the older doctors performed each in his own community. Both the departments of health and the lay organizations did much to irritate the physicians who, on the other hand, often seemed exasperatingly conservative to the public health

practitioners. Until about ten years ago it almost seemed that two classes of physicians would be established. But this calamity was happily averted by the decision of the members of medical societies that they would discharge their civic duties and give medical advice and service along all lines of public health. At present the majority of family physicians are practicing civic medicine to some extent as is shown by their willingness to examine children at clinics and to go before official boards in order to advocate a public health project.

The broad object of a medical society is to promote the practice of medicine along all lines, private and public, individual and civic. A medical society has duties toward its own members and toward the people.

To its members the medical society owes protection and inspiration, and above all, instruction. The county medical society is the post graduate school of medicine for the majority of physicians, and the Medical Society of the State of New York is lending its efficient assistance through the committee on Public Health and Medical Education.

To the public the medical societies are giving the service which was formerly given by the village doctor. When a dozen physicians practice medicine in a village, no one feels a personal compulsion to practice public health and civic medicine, although his conscience tells him that the "Medical profession" to which he belongs must discharge that function. The county medical society, through its committees, and especially their chairmen, practices public health and civic medicine. Moreover, the system provides that someone—the chairman of a committee—shall be charged with the personal responsibility to speak and act for the medical profession.

The county medical societies are finding the field of public health practice preempted by departments of health and lay organizations and friction has sometimes developed when the county medical societies have also entered the field. But the leaders of all the three groups are rapidly developing agreements regarding the peculiar fields of work which belong to each.

The sense of civic consciousness which the older practitioners of medicine had in a high degree has undergone a rebirth in the county medical society, and is already a lusty infant of whom its medical parents may well be proud.

## PERVERTED POINTS OF VIEW

It is difficult to follow the arguments of some editors who knock the doctors in every issue of their publications, but some light is thrown upon their mental processes by a study of their knowledge of the basic sciences on which the practice of medicine is founded. Many of the antagonistic editors are logical in thought and skilled in dialectics, but they start with entirely wrong premises, and assume conditions which are untrue. The falsity of the underlying science of these editors is clearly revealed by the following quotations from one who claims to be a leader in health education.

"Doctors are human. Furthermore they become involved in a system and have to stay in it."

"The fundamental principles of allopathy are unscientific and not in accordance with natural law. In the Standard Dictionary allopathy is defined as 'The system of remedial treatment in which it is sought to cure a disease by producing a condition incompatible with the disease'."

"When unnatural stimulants are used and the blood itself is tampered with hypodermically, the value of such remedies is questionable."

"The processes used by the physical organism in effecting a cure of any complaint are beyond detailed analysis. No physician, regardless of how learned he may be, can tell you much or anything of the physiological laboratory in which the body works out the problem of reclamation."

"We object to medical doctoring when natural drugless methods can more quickly and more safely effect the cure. We emphatically object to methods now in general vogue of tainting the blood stream with a view to making one immune to disease. The body has within itself power to make itself immune to practically every disease if the vitality is raised to its highest possible obtainable degree."

"Most doctors will tell you that if they adhered closely to the methods that were given to them in detail as students, their patients would suffer in consequence."

"At present doctors profit by sickness. When their business is bad, people are too healthy."

"The commercial side of the doctoring business often begins to work higher up. The men who pull the wires to scare the people into being vaccinated, and adopt other medical measures through fake epidemics, they are the real criminals. They are traitors. Health and life mean but little to them."

"It is criminals of this sort that this publication is arrayed against to the very last degree."

These quotations express the creeds of most cultists and health faddists, expressed by an editor who is an expert advertising writer. They are reproduced in this column simply to inform physicians of the beliefs which impel their patients to refuse themselves of some of the most striking methods of scientific medicine and to delay seeking a diagnosis and treatment until the curable stage has passed.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*Fitness for Driving Automobiles* — Twenty years ago there were apparently few legal restrictions imposed on the drivers of either locomotives or automobiles. Accidents to paretic drivers were frequent and examinations for the licenses of drivers were seriously considered. Concerning the drivers of automobiles this Journal for October 1907 says editorially:

"The automobile rushes through the streets and country in the hands of any one who lays himself to the task. The number of accidents is appalling. The driver may be half blind, deaf, or paretic—there is no restriction. The large number of fatalities are all in the day's work, so long as we do not know the parties involved, but still we may be the next victims, and then it becomes a different matter. No person should be permitted to run an automom-

bile faster than four miles an hour within the town limits who has not been subjected to a physical examination and determined physically fit and free from disease which does or might suddenly incapacitate him. A medical examination should be necessary for a license, and the license should be good for one year. This need not be burdensome or expensive, and it would surely be for the public good. Our anti-paternalist might object to such an ordinance, but after he is run into by a cross-eyed paretic he will be convinced, if he survive."

The people of New York State have taken precautions regarding the fitness of locomotive engineers, but they are still groping for efficient means to control the drivers of automobiles.

# MEDICAL PROGRESS

**Simple Uncomplicated Rotary Dislocation of the Atlas**—R H Jackson emphasizes the fact that this form of dislocation of the atlas occurs more commonly than is supposed and may be overlooked. If the lesion is not reduced, sudden death may occur from an increase in the dislocation or the development of myelitis months or years after the injury. The anatomical points to be kept in mind are that the transverse process and lateral mass of the atlas on the side of the dislocation are displaced forward, while on the opposite side these structures slip somewhat backward, thus making relatively prominent that portion of the axis which lies immediately below. These two points may be ascertained by a digital pharyngeal examination when it is possible to insert the examining finger. In rotary dislocation the transverse process may be plainly felt on the side from which the head is turned. On the opposite side the fingers are said to sink in deeply and forward, but Jackson was not able to verify this in all his cases. The spine of the axis is deviated to the side from which the head is bent. The true nature of the lesion can often be demonstrated roentgenologically. It was impossible, however, in the four cases reported by the author, to open the jaws sufficiently wide to permit a satisfactory anteroposterior view. Reduction should be delayed at least three or four weeks, and in the meantime constant extension should be applied. In three of Jackson's cases in which the usual method of reduction (the administration of general anesthesia and gentle traction on the head with rotation) failed, Binne's method was used with success. This method consists in thrusting the patient's head through an opening in a laparotomy sheet, reducing the size of the opening by sutures of strong cord so that it fits snugly around the base of the occiput, and then exerting traction on the sheet. This is done by two attendants, standing on operating tables on either side of the patient, while counter extension is exerted by other attendants bearing down on the patient's shoulders. If closed reduction cannot be effected, open operation should be performed, as was done in a case reported by Osgood, and also in a case operated upon successfully by James A Jackson. The procedure consisted in exposing the forwardly displaced posterior arch of the atlas through a four-inch incision in the median line of the neck, and passing an aneurysm needle carrying a stout braided silk around the arch, between it and the spinal cord. Then, while forward pressure on the anterior arch was exerted through the pharynx, traction was made on the posterior arch. Reduction was maintained by tying the silk band

about the hooked spinous process of the atlas—*Surgery, Gynecology and Obstetrics*, August, 1927, vol xlv, p 2

**Ethylene as an Anesthetic for General Surgery**—As a result of their experience with ethylene in 11,607 cases, in 70 per cent of which this anesthetic was used alone, Hugh Cabot and Henry K Ransom conclude that ethylene has all the advantages of nitrous oxide and oxygen. It gives greater relaxation than nitrous oxide and avoids objectionable cyanosis. It appears to be remarkably free from danger except possibly that resulting from explosion, it is absolutely necessary to avoid naked flame or sparks in or near the operating room. It will not give complete muscular relaxation, particularly for operations in the upper abdomen, and if this is required, it must be combined with local or regional anesthesia or another anesthetic selected. With the use of ethylene there is an initial rise in blood pressure on the average to 17 per cent. This rise occurs promptly and falls rapidly. This has some bearing on the value of the anesthetic in the presence of shock, and the substance may be accepted as preferable to ether or chloroform under these conditions. Investigations have shown that ethylene has a less deleterious effect on kidney function than ether. The authors have no record of the occurrence of postoperative pneumonia in any case in which ethylene alone was employed. In their practice it has practically pushed nitrous oxide from the field and will, they believe, supersede it for ordinary surgical operations. As ethylene can be employed only where trained anesthetists are available, it is not likely that it will displace ether or chloroform for use outside of hospitals, but for general hospital practice it has outstanding advantages.—*Annals of Surgery*, August, 1927, vol lxxvi, p 2

**Traumatic Rupture of the Normal Spleen**—Hamilton Bailey (*British Journal of Surgery*, July, 1927, vol xv, p 57) presents an analysis of 32 cases of traumatic rupture of the spleen, three of which were under his own observation. He casts doubt on the prevailing opinion that ruptured spleen is of common occurrence in malarial countries, while he finds that it is frequent where industry prevails. Cases conveniently divide themselves into four groups: (1) The patient rapidly succumbs, never recovering from the initial shock, (2) initial shock, recovery from shock, signs of ruptured spleen, (3) the signs of an intra-abdominal catastrophe are delayed, (4) spontaneous recovery. More than

three-fourths of the cases belong to the second group. As the general signs of ruptured spleen are unreliable, the local signs become important. Abdominal rigidity is present in more than one-half of the total cases and is often most prominent over the lower left abdomen, local tenderness is very common, shifting dullness in the flanks is probably regularly present. The Ballance sign is so rarely present that it is valueless. Abdominal distention begins to appear three or four hours after the accident. Kehr's sign (referred pain in the the left shoulder) is occasionally very much in evidence. In the delayed case, "friable pedicle" seems to be the peculiar terror, and particular care should be exercised to avoid this calamity by making a series of small individual ligatures, applied by transfixion with a sewing needle close to the spleen. If the pedicle cuts through, it may be possible to retrieve it by the Mayo method of dealing with the slipped renal pedicle. Spontaneous recovery is so rare that it may be assumed that splenectomy is always indicated. For this the midline incision is usually adequate. If time permits it is advisable to examine the tail of the pancreas, and if this is damaged many complications may be minimized by a tube brought out on the left flank. While blood transfusion as soon as the pedicle is ligated is the ideal procedure, subcutaneous saline infusion is a good substitute, it should be started at the beginning of the operation, and continued after the conclusion of the operation, if deemed necessary. The early complications are peritoneal effusion, "burst abdomen," left pleural effusion, persistent hiccup, and splenic asthenia. The late complications are attacks of palpitation when lying on the left side, fleeting bone pains, and attacks of vomiting. The majority of patients who have been traced report that they are in good health. In no instance is there the slightest indication that a splenectomized person is more susceptible to infection than the rest of humanity.

**Chronic Pancreatitis** — In describing the treatment of chronic pancreatitis, H. E. Griffiths (*Lancet*, July 23, 1927, vol. ccxiii, p. 5421) points out that this affection always appears to be secondary to some other chronic inflammatory process in the abdomen. This is usually a disease of the gall-bladder, sometimes of the pylorus, and occasionally the cause seems to be in the appendix. The primary focus must first be removed, and then the diseased pancreas must be coaxed back to health by strict attention to diet, by drainage and drugs. The diet must be chosen with the main object of relieving the strain on pancreatic digestion and limiting the amount of intestinal decomposition. Crisp carbohydrate foods, eaten cold, are particularly recommended, such are bread, cut thin and toasted, and breakfast foods having a maize base. The amount of fats should be reduced to a minimum

and all fat should be excluded from protein meals. Meat may be taken sparingly once a day, eggs should be avoided. Fruit and green vegetables may be eaten sparingly. Milk, tea, beer, stout, and sparkling wines are forbidden. Drainage is obtained by the use of the duodenal tube or by operation. Griffiths employs the Lyon method and finds that peptone is often more active than magnesium sulphate in stimulating the flow of pancreatic juice. Drainage by operation should be done at the time of the primary operation for dealing with the focus from which the chronic pancreatitis arises. In the majority of cases the operation is for cholecystitis complicated by gallstones. If chronic pancreatitis is present, as it usually is in cases of long standing, drainage of the biliary passages is imperative. The failure to relieve digestive symptoms by cholecystectomy is generally due—and this is important—to the overlooking of pancreatitis and the failure to provide and maintain adequate drainage. Where there is any possibility of the ampulla of Vater or the terminal part of the common bile duct becoming occluded by the pressure of a sclerosing pancreatitis or other cause, the gall-bladder must be preserved, as it may ultimately be necessary to resort to cholecystoduodenostomy. Drainage must be maintained for several weeks. Where pain is a prominent feature of chronic pancreatitis, relief may be obtained by incising the peritoneum on the antero-superior surface of the pancreas. Drug treatment has for its object disinfection of the pancreatic ducts and control of intestinal putrefaction. Sodium salicylate and aspirin are the most valuable pancreatic disinfectants. Victor Schekter recommends the following: the juice of four lemons, 20 grains of sodium salicylate and 30 grains of sodium bicarbonate, to which, when effervescence has ceased, is added one bottle of Vichy water. This quantity should be consumed in the course of 24 hours. Two drugs of particular merit for the control of intestinal putrefaction are oil of cloves and calomel in small doses.

**Sepsis from Pfeiffer's Bacillus** — A. Lechner and A. Boetzel write briefly on this subject in the *Muenchener medizinische Wochenschrift*, July 15, 1927. The role of this particular micro-organism in the production of this blood state is a very modest one. In the great influenza pandemics sepsis from this cause has hardly been seen and the case reported by the authors cannot be classed clinically as influenza. The bacillus appears at times to figure in a rare symbiosis with *Streptococcus viridans* which the authors discuss at length. In the case described no viridans streptococci seem to have been present and the disease was masked as typhoid fever. The patient was a strong woman of 42, admitted under suspicion of typhoid but the agglutination tests were negative for both typhoid and paratyphoid.

No local symptoms appeared for the first ten days aside from the fever which was of a remittent type, but then some cardiac murmurs were heard. The first blood cultures failed, but finally Pfeiffer's bacilli were cultivated. After the third hospital week cerebral symptoms appeared—hemiplegia followed by meningism. Death followed after a total illness of 8 weeks (2 weeks of fever before hospitalization). Autopsy showed a valvular verrucous endocarditis with infarcts of the kidneys, perisplenitis, and other evidences of sepsis. Despite the negative Widal the authors up to the time of the positive blood test were almost certain that they were dealing with a case of typhoid fever. The lungs were intact save for terminal edema. However, at the close the syndrome was seen to be that of endocarditis *leita* even without the autopsy finds (progressive, anemina, petechiæ, focal nephritis, etc.). Without discussing the cause of influenza it is manifest at once that the picture here has nothing in common with the fatal cases of that infection.

**Human Infection with Bang's Bacillus**—Professor E. Kreuter, a surgeon in the City Hospital of Nuremberg, refers to the fact that human infection with Bang's bacillus, the cause of infectious or pestilential abortion in cattle, is rare. Before the cases were reported, human infection was unknown in Europe, although a few cases had been reported in America. Bang first published his account of the exciting cause of the disease in cattle in 1896. Of the greatest interest is the close resemblance between the Bang infection in mankind and Malta fever, the cause of which is the *Micrococcus melitensis*, discovered by Bruce in 1887, this microorganism is known to infect goats, being often present in raw goats' milk. The two organisms closely resemble each other, as first pointed out by Alice E. Evans in 1918, but although the resemblance is closer than that between typhoid and paratyphoid bacilli, no assertion of identity or mutation has been put forward. The author now reports a case seen by him in a veterinary surgeon who had been treating a cow who had suffered a febrile abortion. There was a long incubation period before an influenza-like attack set in which was very mild and without loss of appetite or weight. But in the second week of the affection the symptoms became aggravated, and the disease was a puzzle until a parallel case in another exposed veterinary practitioner pointed to an animal origin, agglutination tests revealing the Bang bacillus in the serum. The first attack lasted three weeks and after an interval of complete health a second attack developed and two other recurrences duly followed, one complicated with orchido-epididymitis. The only other complication mentioned seems to have been a mild nephrosis. Blood cultures proved negative throughout, the diagnosis depending on the posi-

tive agglutination test — *Klinische Wochenschrift*, July 16, 1927

**Etiology of Annexitis**—L. Gross of Leipzig quotes from an old author (1870) to the effect that about 3 out of 4 of these cases develop either post partum or post abortum. At that period nothing was known of the role of the gonococcus in this pathology. After bacteriology was under good headway attempts were made to base a classification on the organisms found in the pus, but unfortunately a majority of all cases showed pus which was sterile. As something like 20 per cent showed gonococci it was assumed that the sterile cases had originally had the same origin and no less than 80 per cent of annexitis was set down as of venereal origin. Better technique reduced the sterile percentage to about 15, while but 21 per cent was charged up to gonococci, including proved and probable cases. Apparently nearly half of all cases were brought into some relationship with anaerobic organisms of the type found in ordinary wound infections. The status of the entire subject being far from satisfactory, some fresh investigations have been instituted at the Sellheim clinic. Certain cases were eliminated outright as those associated with infected myoma and cancer of the uterus, appendicitis, tuberculosis, etc. The percentage of gonorrheal infection, proved and probable, was twenty-three. Puerperal non-gonorrheal cases made up 58 per cent. In regard to the role of anaerobic organisms the figure was given as 74 per cent. In this research both the organisms present and the clinical histories were duly honored and an attempt was made to harmonize the entire material from 1890 to 1905 by synchronizing the incidence of these cases with the general incidence of abortion, febrile abortion, puerperal fever, gonorrhea, etc., as shown by graphs. Annexal disease is a notable factor in the causation of puerperal infection, so that vicious circles must be thought of. Febrile abortion leads to death in about 9 per cent, while 21 per cent more develop annexal disease. The role of gonorrhea has greatly declined in importance — *Munchener medizinische Wochenschrift*, August 5, 1927

**Postinfectious Cerebral Complications in Children**—Dr. C. Bohnheim of Berlin has been at work on this subject for the past three years, using the material of the Children's Hospital. Since a report made in 1925 he has assembled eight personal observations in which, in the course of the familiar contagious diseases of childhood, mild or severe cerebral symptoms developed. It was at first thought that these complications were almost peculiar to varicella, vaccinia, and variola, but extended observation has shown that this is far from being true. The first four of the eight cases were examples of measles and the cerebral manifestations were

mild and followed by complete recovery. These four cases were a continuation of an earlier series of 11, reported in 1925. One of the four little patients presented a picture of encephalitis, but in this case there was a double mastoiditis as well. The fifth patient had scarlet fever and the cerebral symptoms were mild and recovery was complete. The sixth and seventh of the series had whooping cough and both children presented encephalic symptoms, although fortunately both made complete recoveries. In cases reported by others whooping cough was followed by blindness, idiocy, etc. Finally the eighth patient had chickenpox and developed the picture of lethargic encephalitis although with complete recovery. In none of this series were there any meningeal symptoms. No case has been seen by the author to follow mumps, although other pediatricists have recorded such. In a ninth case, not included in the preceding series, it was first thought that a vaccination meningo-encephalitis had occurred, but autopsy showed the case to have been one of tuberculous meningitis. The symptoms appeared on the fifth day after a primary vaccination in a child aged  $3\frac{1}{2}$  years, which is far too short an interval to conform to the average of post-vaccinal cerebral symptoms. It is of course possible that the reaction to vaccine activated tubercle bacilli, but such a sequence is almost unique—*Klumsche Wochenschrift*, August 13, 1927.

**Possible Identity of the Spirochetes and Fusiform Bacilli of Vincent's Angina.**—Professor G. Sanarelli of Rome discusses this possibility exhaustively. It is difficult to visualize how and why two quite different types of nosoparasite should invariably be in constant pathogenic association. The author has attacked the problem indirectly through the study of the cecal spirochete which can be seen in certain culture media to become transformed into fusiform bodies which are indistinguishable from fusiform bacilli. The spirochete of Vincent's disease may not be a true spirochete. The germs may be two separate forms of a microorganism thus far unknown. The author assumes that such exists and terms it *Heliconema vincenti*. It is of course possible to make pure cultures of each kind, but study of such cultures shows an identity of behavior. In vitro the author has shown how the presence of the *Bacillus mesentericus vulgaris* is sufficient to transform the spiral into the fusiform shape of the heliconema. The symbiosis of a protozoon with a bacterium such as is supposed to underlie Vincent's disease has always seemed far fetched, but to which group does the heliconema belong? Possibly to a separate order. In some respects it resembles the fungi, which naturally are vegetable. It is able to attack the throat and produce ulceromembranous lesions like certain forms of bacteria. Spindle forms have been seen or the most dis-

similar microorganisms which cannot be grouped by form alone. It is evident that a vast amount of work will have to be done before this matter is straightened out, so that for the present the author's unicistic conception will constitute a sort of working hypothesis to be sustained or antagonized—*Annales de l'Institut Pasteur*, July, 1927.

**Extramedullary Hematopoiesis in Anemias.**—In connection with the study of a unique case of large tumor-like growths of hematopoietic tissue in an anemic infant with splenomegaly and an enlarged liver, associated with rickets and malnutrition, and a contrasting case of extramedullary blood formation in an anemic adult, Dorsey Brannan presents certain interesting observations on blood formation in infants. He points out that extramedullary hematopoiesis is a fairly common finding in certain anemias of infancy and childhood, and large tumor-like growths of hematopoietic tissue may occur particularly in the hiluses of the kidneys and, in his case, were found in the falx cerebri, thymus, and lymph nodes. From the findings in the broad ligaments, breasts, and elsewhere, it would seem possible for similar masses to arise in these locations also. Microscopically, the masses were composed of all the blood-forming cells except the large mononuclear, transitional or endothelial cells. In non-anemic infants apparently normal blood formation has been observed in the broad ligaments, breasts, prostate gland, kidneys, epididymis, palms, and soles. These structures should always be examined in anemic infants, especially in cases showing evidence of myeloid changes elsewhere. The special sites of predilection in adults for extramedullary blood production have been very much the same as in the young. The liver and spleen were especially important organs, while in the lymph nodes and kidneys the changes were less common. In the author's second case myeloid activity occurred in the broad ligaments and parametria and in organizing thrombi of the broad ligament. The bone marrow both in the young and in the adults presented a variable appearance. Where an active marrow was found, it seems logical to assume that the marrow was unable to keep pace with the blood destruction, and because of insufficient blood production, there had resulted reversion to the fetal type of blood formation. Hence extramedullary blood production may be regarded as a compensatory reaction. In the broad ligaments of the adult and infants, Brannan found isolated foci of erythropoiesis and leucopoiesis clearly defined. He concludes that in extramedullary hematopoiesis, either erythropoiesis or leucopoiesis, the process appears to start in foci of type cells, which substantiates previous observations regarding blood formation in the bone marrow—*Bulletin of the Johns Hopkins Hospital*, August, 1927, xli, 2.

Counsel, Medical Society of the State of New York

## EARLY HISTORY OF THE NEW YORK STATE MEDICAL SOCIETY

As early as 1749 the doctors of New York City had associated themselves in a medical society, and there is a record of a paper that was read before this body in that year entitled "An Essay on the Nature of Ye Malignant Pleurisy that Proved so Remarkably Fatal to the Inhabitants of Huntington, L I, and some other places on Long Island, in the winter of the year 1749" This society appears to have continued in existence and to have held regular meetings down to the year 1794, when on November 14th the first organization to bear the name of the "Medical Society of the State of New York" was organized

The minutes of the first meeting of that organization record that "A number of medical gentlemen, wishing to associate for the purpose of promoting friendly professional intercourse, determined to meet at the City Hall on the evening of November 14, 1794, where there appeared Drs John Charlton, Thos Jones, Samuel Bard, Malachi Treat, Richard Bayley, Louis Faugeres, James Tillary, Samuel Nicoll, Ab Bainbridge, David Brooks, Wm P Smith, John Gamage, Wm Hammersley, John Onderdonk, George Anthon, J R B Rodgers, Wm Post, Wm Lawrence Dr Charlton was appointed chairman" It was resolved at this meeting that the medical society that had theretofore existed should be dissolved, and that the doctors present should form themselves into a new society "by the name and style of the Medical Society of the State of New York, and that they will use the seal of the same"

This society appears to have taken a prominent part in the medical life of the growing city, and to have interested itself at an early date in public health questions, especially those which pertained to the ravages of epidemic diseases. In 1795 we find the Governor of New York State appealing to this organization to cooperate in the suppression of an epidemic prevailing in the upper part of the city as a result of which commercial relations between New York and Philadelphia temporarily had ceased. A committee was appointed to arouse the Mayor, aldermen and commonalty of the City of New York to the danger of epidemics and to the need of providing methods for their prevention

In the same year we find this society writing to the Mayor calling his attention to the causes of the late epidemic "The accumulation of filth in the streets," it wrote, "this being composed chiefly of dead animal and vegetable substances, is when exposed to a hot sun, a source of noxious effluvia, which has a tendency to produce the most fatal effects That such effluvia has been the cause of fever has been confirmed by repeated observation and experience in all parts of the world" They also spoke of 'Obstructed water drains, by occasioning stagnant water, and collecting matter of various kinds which, undergoing decomposition, emit air of qualities extremely prejudicial to health

The records of this society are of surprising interest to the student of public health They reveal that more than a century and a quarter ago the New York physicians were concerning themselves with the problem of safeguarding the health of the people

These records also reveal at what an early date the problem of medical licensure was considered Thus, at a meeting held on January 14th, 1800, the society took notice of the fact that its members had frequently been applied to for the purpose of recommending assistant surgeons in the army and in the navy, and a resolution was adopted that "the members of this Society will not recommend any person as qualified to act in the aforesaid capacity, unless he shall have received a medical diploma from some college or university, or produce a certificate of his having been regularly examined by three of the members of this Society"

The problem of medical licensure in its general application was considered at a meeting of the society held on July 12th, 1803, when it was "Resolved, that a committee of five members be appointed to take into consideration the propriety for applying to the Legislature of this State for a law, regulating the practice of Physic and Surgery, or a law of incorporation, and report at the next meeting" Nothing seems, however, to have come of this resolution, but a statute carrying its purposes into effect, as we shall presently see, was enacted three years later

Contrary to an impression which frequently has prevailed, however, the present New York

State Medical Society was not the outgrowth of the first society using that title. The doctors who in 1794 had organized themselves under that name, were all residents of New York City. The origin of our present State Society is traced to the County of Saratoga.

In the latter years of the eighteenth century, the immigrants who migrated "West," that is, into the upper and western regions of New York State, became an easy prey for charlatans. Imposters who had never read a volume of medicine preyed upon the credulity of these people, and not only obtained an extensive practice, but a reputation also as great healers. "Consultations," said an early record, "were generally distinguished for gross controversies at the bedside of the patient, whose health and life were often immolated to the ignorance, prejudices or discordant theories of the contending physicians. Their skill was generally graduated by their ability to magnify the cures they had made." As early as 1796 the ignorance of those posing as physicians became the subject of general concern in Saratoga County, and in that year the newspapers of that region were calling attention to the need of instituting medical societies for the prevention of these evils. One such society was organized, but its dissolution followed shortly.

Finally, on November 7th, 1805, a meeting of the physicians of the County of Saratoga was convened at the Courthouse in Ballston "for the purpose of devising means to improve the practice of medicine." A committee of correspondence was appointed to communicate with the physicians of Washington and Montgomery Counties. The letter addressed to them recommended to their "earnest attention" the necessity of adopting some vigorous measures for the suppression of empiricism, and the encouragement of regular practitioners. The evil calls loudly for the united efforts of all who sincerely wish to remove from that valuable science the imputation of quackery, under which from the ignorance of some of its professors, it not unjustly labors. The wish of the meeting is to procure from the Legislature of the State their sanction to a medical society, and we request your attendance at the courthouse in Ballston on the 16th of January, 1806, at ten o'clock A. M., either in person or by a committee of your county, for the purpose of adopting the best means for obtaining an act of incorporation."

In conformity with this notice, a delegation of the three Counties of Saratoga, Washington and Montgomery convened at Ballston, on January 16th, 1806, and a memorial was declared to the Legislature for an act of incorporation of the New York State Medical Society, and on April 4th of that year, an act was

duly passed effecting the incorporation. The recital of the bill declared that "Whereas, well regulated medical societies have been formed to contribute to the diffusion of true science, and particularly the knowledge of the healing art," therefore, the act of incorporation was granted.

The medical societies of the various counties were duly recognized, and express power was given each of them "to examine all students who shall and may present themselves for that purpose, and to give diplomas under the hand of the president and seal of such society before whom such student shall be examined, which diploma shall be sufficient to enable the person so obtaining the same to practice physic or surgery, or both, as shall be set forth in the said diploma, in any part of this state." Each county society was authorized to appoint not less than three nor more than five censors "whose duty it shall be carefully and impartially to examine all students who shall present themselves for that purpose, and report their opinion in writing to the president of the said society." It was also provided that any student whose qualifications were deemed insufficient by a county society and who thought "himself aggrieved by the decision of such society," could in the nature of an appeal, secure an examination from the state society which, if it deemed the applicant sufficiently qualified, might grant him a license to practice.

No penalty was provided for the unlawful practice of medicine, except that a person not licensed was "disqualified from collecting any debt or debts incurred by such practice in all courts of this state."

In order to insure that only those of requisite education should be eligible for examination, the act expressly declared that an applicant for examination must first produce "satisfactory testimony that he has regularly studied physic or surgery or both, as the case may be, with one or more reputable practitioner or practitioners for the term of three years."

Although the meeting of the physicians from the three counties held at Ballston had not contemplated a law of state-wide application, the committee appointed by that meeting assumed (fortunately, as it turned out) the responsibility of petitioning for and securing a statute embracing the entire state. It is not surprising, however, that the New York County Society which, as we have seen, since 1794 had been known as the New York State Medical Society, looked with some misgiving at the law which had appropriated their name for a state-wide organization, but at an adjourned special meeting, after much deliberation, the New York City organization acquiesced in the new statute, and our present State

## EARLY HISTORY OF THE NEW YORK STATE MEDICAL SOCIETY

As early as 1749 the doctors of New York City had associated themselves in a medical society, and there is a record of a paper that was read before this body in that year entitled "An Essay on the Nature of Ye Malignant Pleurisy that Proved so Remarkably Fatal to the Inhabitants of Huntington, L I, and some other places on Long Island, in the winter of the year 1749" This society appears to have continued in existence and to have held regular meetings down to the year 1794, when on November 14th the first organization to bear the name of the "Medical Society of the State of New York" was organized

The minutes of the first meeting of that organization record that "A number of medical gentlemen, wishing to associate for the purpose of promoting friendly professional intercourse, determined to meet at the City Hall on the evening of November 14, 1794, where there appeared Drs John Charlton, Thos Jones, Samuel Bard, Malachi Treat, Richard Bayley, Louis Faugeres, James Tillary, Samuel Nicoll, Ab Bainbridge, David Brooks, Wm P Smith, John Gamage, Wm Hammersley, John Onderdonk, George Anthon, J R B Rodgers, Wm Post, Wm Lawrence Dr Charlton was appointed chairman" It was resolved at this meeting that the medical society that had theretofore existed should be dissolved, and that the doctors present should form themselves into a new society "by the name and style of the Medical Society of the State of New York, and that they will use the seal of the same"

This society appears to have taken a prominent part in the medical life of the growing city, and to have interested itself at an early date in public health questions, especially those which pertained to the ravages of epidemic diseases In 1795 we find the Governor of New York State appealing to this organization to cooperate in the suppression of an epidemic prevailing in the upper part of the city as a result of which commercial relations between New York and Philadelphia temporarily had ceased A committee was appointed to arouse the Mayor, aldermen and commonalty of the City of New York to the danger of epidemics and to the need of providing methods for their prevention

In the same year we find this society writing to the Mayor calling his attention to the causes of the late epidemic "The accumulation of filth in the streets," it wrote, "this being composed chiefly of dead animal and vegetable substances, is when exposed to a hot sun, a source of noxious effluvia, which has a tendency to produce the most fatal effects That such effluvia has been the cause of fever has been confirmed by repeated observation and experience in all parts of the world" They also spoke of 'Obstructed water drains, by occasioning stagnant water, and collecting matter of various kinds which, undergoing decomposition, emit air of qualities extremely prejudicial to health

The records of this society are of surprising interest to the student of public health They reveal that more than a century and a quarter ago the New York physicians were concerning themselves with the problem of safeguarding the health of the people

These records also reveal at what an early date the problem of medical licensure was considered Thus, at a meeting held on January 14th, 1800, the society took notice of the fact that its members had frequently been applied to for the purpose of recommending assistant surgeons in the army and in the navy, and a resolution was adopted that "the members of this Society will not recommend any person as qualified to act in the aforesaid capacity, unless he shall have received a medical diploma from some college or university, or produce a certificate of his having been regularly examined by three of the members of this Society"

The problem of medical licensure in its general application was considered at a meeting of the society held on July 12th, 1803, when it was "Resolved, that a committee of five members be appointed to take into consideration the propriety for applying to the Legislature of this State for a law, regulating the practice of Physic and Surgery, or a law of incorporation, and report at the next meeting" Nothing seems, however, to have come of this resolution, but a statute carrying its purposes into effect, as we shall presently see, was enacted three years later

Contrary to an impression which frequently has prevailed, however, the present New York

first degree burn on her shoulders and neck half-way down to scapula on both sides, under her chin in the front down to the clavicle. An examination of the ammoniated mercury disclosed that she had used about a half teaspoonful which could not cause the burn of which she complained. The patient made no statement to the physician as to how the burn occurred.

Over the burned area the physician applied carron oil, unguentine and bicarbonate of soda. The physician remained with the patient for about an hour, and because of her hysterical condition gave her a hypodermic of morphine.

Upon the following day when he called, the patient was not at home, and several subsequent attempts to communicate with her by telephone were unsuccessful. He heard nothing further of this patient until a malpractice action was instituted against him.

In this action it was charged that the defendant, as a physician, had been engaged to attend and treat the plaintiff for an illness from which she suffered, but that he was negligent and careless in his treatment and his prescribing for her, that the remedy he prescribed aggravated her malady, and caused unnecessary soreness about the neck, throat and chest. It was charged that it was improper for the plaintiff's condition for the defendant to have prescribed the ointment of ammoniated mercury, that it was likewise improper to have applied iodine, and that by reason of the defendant's negligence, the plaintiff claimed to have been damaged.

This action, following the course of many similar ones, not being pressed for trial, a motion was made to dismiss it for failure to prosecute, which motion was granted, terminating the action in the defendant's favor.

---

### TONSILLECTOMY—REMOVAL OF THE UVULA

In this action it was charged that the defendant was engaged by the plaintiff, and after examination he advised the plaintiff that it was necessary that the plaintiff's tonsils be removed. It was further charged that during the course of the operation and through the negligence of the defendant, the plaintiff's palate was removed and that by reason of the removal of the palate the plaintiff has suffered great physical and mental pain, caused great discomfort in eating and drinking and that his sense of taste and power of voice have been greatly injured, that he has constant throat pains and paralysis of the throat, that he was otherwise damaged and seeks by this action to be compensated by the defendant for his injuries.

This patient had come under the care of the defendant physician and upon examination it was found that his tonsils were infected. They were treated for a period of about a month and a half and at several times during this period the defendant physician pressed pus out of the tonsils and applied tincture of iodine in the tonsil pits. Towards the end of the period of treatment, the physician advised the removal of the tonsils and under a general anaesthesia performed a tonsillectomy. He stated that he dissected the tonsils and with a Mosler snare completely removed both tonsils and that he was positive that he did not injure

or cut the palate during the performance of the tonsillectomy. There was no unusual bleeding and the patient came out of the anaesthesia in a short time. He left the hospital in a day or two after the operation. The defendant again saw the patient about five days after the operation and again a month after the operation, at which last time he found the throat healed and did not recall anything unusual about the patient's palate. His bill for the treatment and operation remained unpaid.

In a physical examination made of the plaintiff about two and a half years after the operation, it was found that no palate or uvula was present. The examining physician was of the opinion that the amputation of the uvula caused no discomfort or difficulty whatever, that its loss was a minor quality. He found, however, that the soft palate had not been injured, that it was full and rounded and did not show any scars where the uvula had been amputated from it. From the test made by the examining physician, he did not feel that the patient's voice had been affected by the removal of the uvula.

For a while the plaintiff and his attorney were vigorous in their prosecution of the action. Finally, when it was about to be reached for trial, they being unsuccessful in procuring a settlement, the action was discontinued.

Society was launched upon its notable and honorable career

Thus, during the administration of President Thomas Jefferson, from the determination of far-seeing medical men to rid their profession of quackery, to provide for proper medical licensure and to effect a cohesive state-wide

organization, our present State Society was born. It was founded "to contribute to the diffusion of true science, and particularly the knowledge of the healing art." Greater even than the founders dreamed was the contribution that has come from the society which was thus brought into being.

---

### FOREIGN BODY IN HAND

The patient charged that he had called upon a physician for the purpose of having a piece of lead removed from the palm of his hand which had become lodged therein while he was engaged at his work, that the defendant physician negligently and carelessly cut and operated upon the hand, and advised the patient that the foreign body had been removed, that shortly after leaving the physician, the patient's hand began to swell, and that he was compelled to engage the services of another physician who operated upon his hand and removed the piece of lead therefrom. He claimed that by reason of the defendant's negligence, he was required to expend money for other physicians, and was prevented from following his employment.

One evening while the defendant was attending a patient at a hospital, the plaintiff came to the clinic of the hospital, the clinic at that time being closed, and stated to the superintendent that he had a sore hand and wanted medical attention. The superintendent of the hospital asked the defendant physician if he would attend to the plaintiff. The defendant then took the patient to the operating room. The patient stated to the defendant that the point of a pencil had broken, and he believed that the same was lodged in his hand.

The physician, upon examination of the

palm of the hand, found a puncture about an inch from the ulna and about the middle of the palm. The skin around the puncture was red, but there was no discoloration. The physician manipulated the hand, but could feel nothing. The physician also probed the wound, but could not feel anything upon probing.

Then under a local anæsthesia of ethyl chloride, an incision was made, and the physician probed the wound, but could find no foreign body. Upon completion of this last probing, the physician advised the patient that nothing further could be done for him at that time. He then washed the wound with a lysol solution, and applied iodine and sterile dressings. He further advised the patient that unless the hand became painful or swollen, to call the following day.

The patient being out of work, stated that he was unable to pay for the services rendered which were given gratis. The doctor also advised the nurse that if the patient returned to the hospital and if the hand did not at that time appear healed, that an X-ray should be taken. The defendant physician heard nothing further from the patient until this suit was instituted against him.

When the matter came on for trial, a judgment was rendered in favor of the defendant.

---

### RINGWORM—IMPROPER PRESCRIBING OF AMMONIATED MERCURY

A physician was house surgeon at a hotel and a person employed at the hotel as a manicurist had at various times been gratuitously treated by this physician. About a year after this person had been discharged from the hotel, she called upon the physician at his office. An examination at that time showed that she had three spots on her chin and face of roughened skin which gave the appearance of ringworm. They were circumscribed areas, each about the size of a ten-cent piece. The patient stated that she had previously had medical treatment for the condition, but that the same did not help her, and also that she had used tincture of iodine.

The physician diagnosed the condition as ringworm, and applied tincture of iodine, by means of a cotton swab, left the iodine on for about three or four minutes, and then applied alcohol, and then a little talcum powder. He also prescribed ointment of ammoniated mercury, and instructed the patient to apply it at night.

Later in the same day, the physician received a telephone call from the patient stating that she was burned, and asked the physician to call on her at her place of residence. Upon arrival, the physician found the patient crying and hysterical. An examination disclosed a

Steuben County had supported a post-graduate course, and had prepared a weekly health note to be published in the newspapers of the county

Tioga County had continued its prenatal work that was described at the District Branch meeting last year

Tompkins County had promoted post-graduate study, and had taken steps for the establishment of a county health department

Dr Daniel S Dougherty, Secretary of the Medical Society of the State of New York, said he had been asked the question, "Does the State Society Function?" A concrete reply to that question was the presence of six officers of the State Society at this meeting, and the

necessity that they should make an auto trip of 130 miles to hold an important conference in the evening with representatives of a county medical society, and then another dash of 80 miles to meet with the Seventh District Branch on the following morning. He said that Dr George M Fisher, President of the State Society last year, had spent 115 days visiting county societies and attending meetings of committees. There was seldom anything spectacular or "newsy" about the relations of the State Society to the local organization, but there was much study of local needs, and much time given to advising local societies in matters which appear commonplace when put in print

### THE SEVENTH DISTRICT BRANCH

The Twenty-first Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York, was held in the Geneva Country Club, Geneva, N Y, on Wednesday, September 28, 1927. Dr Claude C Lytle, the President, presided. About 125 members were present out of a District membership of about 700, of whom about two-thirds live in Rochester in the County of Monroe. Luncheon was served in the club house at noon.

The first period of the morning session was given over to the officers of the Medical Society of the State of New York.

Dr James E Sadlier, President, discussed the policies of the State Society, and said that one of the great activities of the Society is to promote the practice of medicine along all lines which have been indicated by modern scientific progress. New developments in the knowledge of the causes of diseases had pushed back the time when a disease could be recognized until now it was possible to discuss their pre-clinical signs, or those which are apparent to the trained physician while the patient is still going about his work. A knowledge of the sources of contagion and modes of infection has shown that their control can be accomplished only by collective action by both the public and the physicians. Hence, organizations of physicians are necessary if the medical profession is to apply all the forms of medical knowledge which it possesses. The alternative is that the public will create a class of doctors who will practice civic medicine at public expense, and this means socialized medicine. The State Medical Society is meeting the situation by encouraging county medical societies to appoint committees on Public Health and Public Relations, whose duties shall be to make public recognition of the health problems of their communities and devise plans for their solution. Fortunately, the

county medical societies are responding to the plans of the State Society, and are demonstrating their public spirit in the practice of civic medicine.

Dr Thomas P Farmer, Chairman of the Committee on Public Health and Medical Education, said that his committee gave concrete expression to the policies expressed by Dr Sadlier, and was seeking to prepare physicians to practice all modern forms of medicine, especially the recognition of common forms of sickness while they were in their incipient stage and curable. The greatest public health service that physicians can render to the public is that of preparing themselves to cope with diseases in their early stages. To this end the committee will provide lectures and courses of instruction along any practical line that a county society may choose. The committee is now working on a plan by which teams of three physicians will be sent out to give lectures on allied subjects.

Dr W W Britt, Chairman of the Committee on Medical Economics, said that one of the most important economic subjects now before the medical profession is the relation of lay health organizations to the practice of medicine, and that its solution consisted in the active leadership in public health by the medical societies.

Dr Britt also outlined the work of his committee in relation to Workmen's Compensation, and especially in combatting the erroneous impression held by labor leaders because a few doctors had come into notoriety in compensation cases. He suggested that every county society have a committee on medical economics. He said that a questionnaire was now being prepared on economics to be sent to the secretary of every county society.

The scientific program consisted of three papers.

# NEWS NOTES

## THE SIXTH DISTRICT BRANCH

The twenty-first round of annual meetings of the District Branches of the Medical Society of the State of New York was begun by the Sixth District Branch, which held its sessions on Tuesday, September 27, 1927, in Johnson City, N. Y., with the President, Dr. Wilber G. Fish, of Ithaca, presiding, and the Secretary, Dr. Hubert B. Marvin, of Binghamton, recording.

The attendance was over 100, out of a membership of about 450 in the ten county societies that compose the District Branch. The Sixth is noted for the large proportion of its members who attend the meetings.

The meetings were held in the George F. Johnson Pavilion, the assembly hall of the Endicott-Johnson Company, shoe manufacturers, and those in attendance were entertained at lunch by the Company in its dining hall.

The first three papers were descriptive of the medical work of the Endicott-Johnson Company. The Company supplies medical service to its employees, and their families free. It has an organized medical department with a personnel of 26 physicians who serve a population of between 25,000 and 30,000 workmen and their families. A nursing service is supplied, and clinics and hospitals are maintained. When specialists are needed, they are called from Binghamton and other cities, and are paid their usual fees by the Company. (A description of the work was printed on page 860 of the September, 1924, issue of this Journal as a part of the medical survey of the City of Binghamton of which Johnson City is an adjoining suburb.)

Dr. Daniel C. O'Neil, Chief of the Medical Service of the Endicott-Johnson Medical Department, read a paper entitled "Industrial Medicine" in which he described the work of his organization. Dr. Arthur W. Booth, of Elmira, in discussing the paper, called attention to the fact that the service was a demonstration of community medicine carried on among about one-third of the people of a community having about 100,000 population. The service seemed to go on naturally and quietly, and physicians engaged in ordinary practice had an open mind toward it. As a matter of fact, there are several physicians doing private practice among the employees who are entitled to free medical service. Statistics of the service seem to show that the average number of patients treated by each doctor, the incomes of the physicians employed

in the medical service, and the total cost of the service to the Endicott-Johnson Company do not differ widely from the statistics of similar services given by physicians in private practice.

The second paper was on the subject of "Feeding During the First Year of Infancy," by Dr. Raeburn J. Wharton, pediatrician of the Endicott-Johnson Medical Department. This paper was discussed by Dr. Mary J. Ross, of Binghamton.

The third paper of the series was on "Painless Childbirth by the Use of Synergistic Analgesia," by Dr. Ralph J. McMahon, of the Company's service. It was discussed by Dr. Stuart B. Blakely, of Binghamton.

Dr. W. Russell MacAusland, Surgeon-in-Chief of the Orthopedic Department of the Carney Hospital, Boston, Mass., gave a paper on "Backache," illustrated with lantern slides. The discussion was opened by Dr. Charles M. Allaben, of Binghamton.

Dr. Russell L. Cecil, of the Cornell Medical School, gave a paper on physiotherapy, and exhibited some of the latest approved pieces of apparatus. The paper was discussed by Dr. Clarence Anderson, of Elmira.

A clinical demonstration of common skin diseases was given by Dr. Howard Fox, of New York City, on patients brought by local physicians.

Dr. James E. Sadler, President of the Medical Society of the State of New York, told about the practical service which the State Society was giving to the physicians of New York State, particularly that of coordinating the work of the county medical societies and encouraging them to undertake the civic duties which the people expect from the medical profession.

Dr. Wilber G. Fish, in his presidential address, enumerated some of the more striking activities of the county medical societies beside those in connection with their meetings.

The Broome County Society had conducted a pediatric course of lectures, and had done anti-diphtheria work.

The Chenango Society had promoted courses in pediatrics and a lecture on cancer.

Cortland County had conducted a cancer lecture, supported anti-diphtheria work, and planned a campaign against goiter.

Otsego County had conducted post-graduate lectures for two years, and supported the anti-diphtheria work.

- 11:00 Surgical rounds in Wards Dr D W Houston, Jr  
Results in decapsulation of Kidney for Nephritis Dr Benson  
Result in case of resection of intestine for Volvulus Dr Willard Smith House Physician  
X-Ray exhibit by Dr T A Hull  
Pathological specimens exhibited in the Laboratory Dr H W Carey

The Leonard Hospital, 75 beds, had the following clinical program

- 9:00 Tonsillectomy Dr Baker  
10:00 Nephrotomy for Removal of Renal Calculus Dr Connally  
10:00 Clinical Demonstration of X-Ray Dr McShane

In addition other public institutions of a medical nature, of which Troy has an unusual number, were open for inspection. These included the Pawling Sanatorium for Tuberculosis, the Marshall Sanatorium for the Insane, three founding asylums, five orphanages, and three homes for aged men and women.

The afternoon program consisted of two parts: 1, a presentation of the policies of the State Medical Society, and 2, a scientific program.

Dr James E Sadlier, President of the Medical Society of the State of New York, spoke on the newer duties of physicians which had developed in the course of the evolution of medicine. The former ethical standard that the patient must seek the doctor, still held good so far as the private practice of curative medicine was concerned, but it was no longer true in the practice of public health and civic medicine. The people must be educated in hygienic subjects, and in the essential service which doctors can render in preventive medicine. They do not seek the doctor in the prevention of distant diseases, largely because they do not realize the scope of the service which a doctor can render. It is entirely ethical that every physician should seek to educate the people medically by means of speeches and writings done in the name of county medical societies. The State Society encourages every county society to enter the

field of medical publicity, and to give out news of the activities of all its committees. That is the standard means for bringing a knowledge of medicine to the people.

Dr Daniel S Dougherty, of New York City, Secretary of the Medical Society of the State of New York, explained some of the misapprehensions regarding the State Society. He said that the Society had sent 2,000 letters to physicians who had neglected to register last year and many physicians had expressed their gratitude for having the matter called to their attention, for they had supposed that the Medical Society would register their names for them.

Dr Dougherty explained the status of the Grievance Committee, and said that it was not a committee of the State Medical Society, but was an official committee under the Regents of the State of New York. The State Medical Society was connected with it only to the extent of nominating some of its members—a privilege which it shared with the Homeopathic and the Osteopathic societies.

Three papers were presented at the scientific session.

Dr James T Gwathmey, Anesthetist to the Skin and Cancer Hospital, New York City, gave a lecture on "Preliminary Medication in General Anesthesia," illustrated with lantern slides and photomicrographs. He gave figures to show that preliminary injections of morphine lessened the shock of the anesthetic and prolonged the period of ease immediately after the operation. Also he said that the hypodermic injection of magnesium sulphate intensified the action of the morphine, and prolonged its effects about four times.

Dr Gwathmey also described the condition of analgesia, as distinguished from anesthesia that followed the rectal injection of a mixture of oil and ether, and said that ether is given off at a constant rate which corresponds to that required for maintaining analgesia.

Dr Walter T Diver, of Troy, read a paper on the treatment of goiter, which will be published later in this Journal.

Dr Harry W Carey of Troy, gave a paper on the "Comparative Results of Treatment of Cancer of the Cervix."

---

## COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

The Committee on Public Health and Medical Education of the Medical Society of the State of New York, held a meeting on September 22 in the Ten Eyck Hotel, Albany, N Y, in order to organize its activities during the coming year. There were present Dr

Thomas P Farmer, of Syracuse, Chairman, Dr John O Polak, of Brooklyn, Dr George F Chandler, of Kingston, Dr Edwin MacD Stanton, of Schenectady, Dr William A Groat, of Syracuse, Dr George F Longstreet, of Binghamton, Dr Sturhipe Bayne-Jones, of

Dr John B Deaver, of Philadelphia, read a paper on "Lower Abdominal Emergencies," which will be published in this Journal. He made a plea for the earlier recognition of appendicitis—a disease in which there is an increasing mortality. He enlivened his paper with interesting side remarks and humorous stories.

Dr Foster Kennedy, of New York City, gave a talk on the "Differential Diagnosis of Organic and Fundamental Symptoms and Signs." Dr Kennedy dwelt on neurological conditions, especially hysteria, which is a typical disorder that is called functional. He enriched his talk by descriptions of cases of so-called "shell shock" in which fixed ideas of paralysis or mutism persist because they afford a means for escaping service at the front. He spoke of the need for a show of great positiveness on the part of the doctor in order to impress his will upon that of the patient.

Dr Kennedy told of studying Coue for two days. The healer was absolutely ignorant of all kinds of science, and resolutely shut his mind to facts, and in this way he maintained

a firm conviction in his own power, and transmitted it to those who were paralyzed because of lack of will power. If ten paralytics received his ministrations, and one had hysteria and got well, Coue would dismiss all thoughts of his failures on the nine patients and would remember only the tenth one.

Dr Ward Crampton gave a talk on the method of making a periodic health examination, and demonstrated it on an actual case.

The following officers were elected for two years beginning at the close of the next annual meeting of the Medical Society of the State of New York.

President, Austin G. Morris, M.D., Rochester.

First Vice President, Ralph Sheldon, M.D., Lyons.

Second Vice President, M. Louise Hurrell, M.D., Rochester.

Secretary, John A. Lichty, M.D., Clifton Springs.

Treasurer, Edward T. Wentworth, M.D., Rochester.

### THE THIRD DISTRICT BRANCH

The Twenty-first Annual Meeting of the Third District Branch of the Medical Society of the State of New York, was held on October first, in Troy, New York. Dr. Edgar A. Vander Veer, of Albany, the President, presided, and the Secretary, Dr. William M. Rapp, recorded. The plan of the meeting was that a series of clinics was held in the several hospitals in the morning, a luncheon in the Hendrick Hudson Hotel at one o'clock, and an afternoon scientific session. The attendance was over 100 out of about 500 members of the seven county societies of the district. The physicians attended the morning clinics in gratifying numbers, from 20 to 30 being at each hospital.

The meeting was in charge of a committee from the Rensselaer County Medical Society, consisting of Dr. Augustus J. Hambrook, President of the Society, Chairman, who gave an address of welcome. Dr. Hambrook's assistants were the past presidents of the society, Drs. Frank M. Sulzman, John H. Reid, John J. Rainey, John D. Carroll, Eugene F. Connolly and Peter L. Harvie.

The programs of the morning clinics at the Troy hospitals were as follows:

At the Troy Hospital, an institution with 350 beds, the clinical program was:

A. M.

9 00 Varicose Veins (Venesection) Dr. C. F. Kivlin.

9 30 Hypertrophied Tonsils (Tonsillectomy) Local anesthesia Dr. J. D. Carroll.

10 00 Ventral Hernia (Hernioplasty) Local anesthesia Dr. C. F. Kivlin.

10 00 Congenital Hip Dislocation, bilateral (Lorenz Method) Gas anesthesia Dr. J. H. Reid.

Chronic Osteomyelitis Humerus (Incision and Drainage) Dr. J. H. Reid.

10 00 Oesophagoscopy for Diagnosis Dr. J. J. Rainey and Dr. J. T. H. Hogan.

10 30 Toxic Adenoma (Thyroidectomy) Gas anesthesia Dr. W. T. Diver.

10 30 Convergent Strabismus (Reese Resection) Dr. J. B. Burke.

11 00 Clinical Eye Condition (Demonstration) Dr. F. M. Sulzman and Dr. J. B. Burke.

11 00 Paragraphia with Paraphasia Dr. H. F. Albrecht.

11 00 Interesting X-Ray Plates (Demonstration) Dr. D. E. Rowan.

The Samaritan Hospital of 350 beds, had the following program:

8 30 Tonsillectomy and Adenoidectomy Dr. Irwin Johnston.

9 00 New Obstetrical Forceps described by Dr. Calhoun.

9 30 Synergistic Anaesthesia and Obstetric Technique, Dr. W. D. Van Auken.

9 30 Diagnostic Curettage for uterine bleeding. Curettement of Femur for old Osteomyelitis Dr. P. L. Harvie.

10 00 Medical Clinic Dr. H. Gordinier.

# MEDICAL WARES

## SUTURES

Closing wounds by sewing is almost as old as surgery itself, but the standard practice of ligating arteries to stop bleeding dates only from Ambrose Pare who, in the year 1552, made the use of the ligature a standard procedure in military surgery. While it had long been known that hemorrhage could be stopped by tying the bleeding artery, yet secondary hemorrhage often occurred days after suppuration took place. Since cauterization sterilized the wound, it was the accepted method of controlling hemorrhage until Pare introduced clean methods of applying ligatures.

Silk and linen were the materials formerly used for ligatures and sutures, for they were not digested or affected by the body fluids, but held as long as shreds of a bleeding vessel remained. These sutures had to be removed from healing wounds, and "taking out the stitches" was often almost as painful as putting them in.

Strings for harps and other musical instruments were made from the intestines of sheep in ancient times. The word for harp in Greek and Latin was *kithara*, and its root, *kit*, appears in the modern words *guitar* and *zither*. The word for guitar string was therefore *kitgut*, which the imaginative musicians changed to *catgut*.

The use of harp strings for sutures was mentioned by Arabian writers over a thousand years ago. These strings were full of septic bacteria and spores, and quickly melted away in the suppuration which they caused. But when aseptic surgery began to be practiced, *catgut* soon became the principal suture material.

The development of practical means of preparing *catgut* was a long evolution in which high-class scientific researches in bacteriology and chemistry were necessary. The connective tissue of the intestine, from which the sutures are made, is an insoluble collagen, which is changed to soluble gelatine when it is heated in the presence of water, and so boiling water could not be used for sterilization. Alcohol at first seemed to be a suitable material, but it nearly always contained water which softened the collagen when it was boiled. Also the short period of boiling did not kill the spores, especially those of tetanus, which are frequently present in the intestines of sheep and other animals.

Chemicals were also given a thorough trial

but they either made the sutures brittle or were ineffective in killing the bacteria. Carbolic acid produced only a surface coagulation which protected the deeper parts from its direct action, and mercury bichloride had the same great disadvantage. It was not until methods of heat sterilization were developed that *catgut* which was sterile, strong, and flexible could be produced.

Crude *catgut* is a standard article of commerce, for it is used in musical instruments, tennis rackets, clock weights, and for other purposes requiring strings of great strength and durability. However, that intended for surgical sutures is made from the intestines of freshly killed sheep with special care and under the most aseptic conditions that are possible.

The spun *catgut* comes to the suture maker in the form of skeins or coils. The first process in the preparation of sutures is to standardize their size. This is done by holding a string tense between the two hands and forcing it into a gauge every foot or two. Seven standard sizes are recognized, having a diameter varying from about one quarter of a millimeter for the size number 000, to two-thirds of a millimeter for number four size.

The strength of the strand is also tested. *Catgut* of the size 000 will support a weight of about nine pounds, while size 4 will support about 48 pounds when tested over the pulley wheel of a Chatillon dynamometer.

The strand is also subjected to the action of solvents which remove its foreign matter, especially the fat which is one of the principal causes of the slipping of knots.

The suture material is cut to standard lengths, dehydrated, and placed with toluol or a similar satisfactory medium in glass tubes which are sealed in a flame. They are then ready for sterilization, which is the most important of all the steps in the preparation of sutures.

Sterilization must be so complete that it kills the most resistant spores without impairing the strength or flexibility of the sutures. A long search for a suitable liquid in which the sutures can be sterilized has resulted in the choice of toluol, a coal-tar distillate. This liquid will not affect the strength and flexibility of the sutures, and it will remain stable under a high degree of heat. It is also volatile and has a pleasant odor and remnants that are left in the sutures will not injure the tissues.

Rochester, and Dr Clayton W Greene, of Buffalo

Dr Farmer explained that the Chairman of the Committee was elected by the House of Delegates, and his eight associates were appointed by the council on the nomination of the Chairman. A member had been appointed from each District Branch. Two of the members were obstetricians and gynecologists, two were surgeons, two practiced internal medicine, one was a health commissioner, and one was a laboratory specialist. The personnel of the Committee was representative in its geographic distribution and in the branches of medicine that are practiced.

Dr Farmer reported that the educational work of the Committee had been highly successful and popular during the past three years under the Chairmanship of Dr Charles A. Gordon. Dr Farmer had done much preliminary correspondence during the summer in order to ascertain the wishes of the members of the county medical societies in regard to the subject of medical education, and had requests from a dozen or more societies for aid in carrying on work in which the Committee was interested. He explained that the public health activities of the Committee were closely related to those in education, and that its specific activities consisted principally in promoting courses of medical lectures for county medical societies. A liberal budget which had been allowed to the Committee, had been used largely for clerical hire and for honorariums and expenses of the lectures.

Dr Farmer said that the direct public health work of the Committee had consisted largely in the encouragement of county medical societies to engage in public health work such as that of the Schenectady County Medical Society in the prevention of diphtheria.

Dr Stanton said that the members of the Schenectady Society had voted to engage in city-wide anti-diphtheria work on the plan that every doctor should be ready to give immunizations in his office, and that the society should approve the action of physicians who would try to influence the patients of his family to take the immunizations. The Medical Society had also made arrangements with the City Department of Health to give immunizations to the poor, and had secured the cooperation of the Red Cross, the Committee on Tuberculosis, the Metropolitan and John Hancock Life Insurance Companies, and other lay organizations. The result was that 1,300

immunizations were reported, of which 77 per cent were done in the offices of the doctors, and 23 per cent by the city Health Department. But the greatest benefit was the favorable attitude of the doctors toward the work, and of the people toward seeking the immunizations.

Dr Chandler said that the Schenectady plan had appealed to the physicians of Kingston, and that the Academy of Medicine of that city was now about to put on a free clinic in the Armory, and had secured the active support of the lay organizations engaged in public health. While the Kingston plan included a free clinic, it was like that of Schenectady in that the work was originated and directed by the physicians.

On motion of Dr Chandler, the Committee voted unanimously to approve the plan of leadership in a public health project which the Schenectady County Medical Society had followed in its anti-diphtheria work.

The Committee then discussed the lectures and courses to be promoted by the Committee. Should they be elementary or advanced?

Should a course consist of six lectures or only four, or even less?

Should the obstetrical and pediatric lectures be continued?

Experience had shown that physicians were influenced in their attendance largely by the attractiveness and clearness of expression of the lectures. Doctors are not medical students who are compelled to learn a subject no matter how dry it may be or how obscure its presentation. But practicing physicians will gladly attend a course of lectures which are presented simply and clearly as were those in the courses in St. Lawrence and Jefferson counties. It was the function of the Committee to discover lecturers who could invest their subjects with interest, and present them in a way which doctors could apply in their daily work.

The decision of the Committee that counties which had asked for lectures on special subjects should be supplied, and that the Committee should offer courses of from two to four lectures on miscellaneous subjects. It further decided that the members should canvass their districts for speakers whose style of teaching was attractive to physicians.

The Committee passed a motion to request the Council and Trustees to make provision for the employment of a permanent secretary to handle the correspondence and business of the Committee.

# THE DAILY PRESS

## SOCIOLOGY FOR POLICEMEN

The New York *Herald Tribune* for August 24 has an editorial on the proposal of a Fordham University professor that sociology should be taught to policemen. The writer credits the policemen with an instinctive knowledge of applied sociology, and says

"In the course of his rounds if he has the wit of the average Irish officer of the law, he acquires a greater knowledge of sociology than all the pedagogues combined. He does not, of course reduce his wisdom to graphs, classifications and theories, he can't discuss with you the 'laws' that govern human nature in its social phases, but he can apply his wisdom with the speed of intuition and the tact of diplomacy to individual cases

which are all he has to deal with until, if ever, he becomes a commissioner, and he can often express it, too, in a homely philosophy, grounded in the soil, or the pavements, and nearer to the truth than any textbook printed

"A fair-sized gulf separates the academic 'science' of sociology from the practical knowledge of human nature and conduct required by a policeman. In a sense, too, they are in conflict. The sociologist should not fail to see the forest for the trees, the policeman on the other hand, should not fail to see the trees for the forest. A fear assails us that a sociological cop on our congested streets would get run over."

## HEALTH OF COLLEGE STUDENTS

College authorities are accepting more and more responsibility for the health of their students. It is only a few years ago that faculties held the opinion that college students were grown men with serious minds that gave due consideration to every influence that prepares them for their life careers. This opinion was seldom justified, for college men are a husky lot to whom a headache or the loss of a few meals and absence from classes for a day or two mean little. However, college faculties have often been embarrassed by discovering unsuspected pneumonia in a boy lying abed because he felt tired, and meningitis in one who had a headache.

Faculties have even adopted the attitude that the college boy is faking when he pleads sickness as an excuse for absence from classes. The professors have the machinery and organization for judging every claim of sickness made by students and absence from classes for half a day should set the diagnostic machinery in motion to seek out the student and find what ails him—whether it is laziness or actual illness.

The importance of health to a student was well expressed by the President of Yale Dr. J. R. Angell, in his address on the opening of the College on October 2, which was reported in the New York *Times* of October 3rd as follows:

What are the talents most essential for an honorable profitable and happy four years at Yale? I do not hesitate to put in the forefront

physical health and vigor. The ascetic and emaciated saint is a historic figure, and there are doubtless forms of spiritual experience which accrue to a complete mortification of the flesh. But, unless one is prepared to defend the morbid view that life itself is unworthy and gladly to be left behind, one must look to bodily health as a blessing to be devoutly sought and scrupulously cherished.

"Not long ago our colleges gave most of their attention in physical matters to the athlete, who least of all stands in need of special opportunity, but now every man has his chance, not only for that refreshment of body and mind which comes from wholesome sport, but also for the constant advice and surveillance of men skilled in the cure and prevention of disease."

Yale University has been a leader in providing medical attention for its students. It maintains a health service with a full-time physician at its head, and offers medical advice and hospital accommodations to the sick. But Cornell University goes much farther than any other college for it has a system of ascertaining the health of the student who is absent or unaccounted for during a single day. It requires the incoming Freshmen to attend lectures on hygiene, and it explains to him the system of health supervision, and the plan works. A description of the system was published on page 31 of the January 16, 1925 issue of this *JOURNAL* in connection with the Medical Survey of Tompkins County.

The sealed glass tubes containing the sutures and the storing liquid are immersed in tanks containing cumol, or a similar liquid, which is heated to a temperature of 165° C (329° F). This temperature is maintained for five hours, while it is constantly watched. It is sufficient to destroy the life of all bacteria and their spores, including those of tetanus. If a surgeon uses sutures in sealed tubes that have been sterilized by heat according to the standard process, he may be confident that they are free from all forms of life, and cannot cause infection of any kind.

Since the tubes of sutures have been heated to a degree far above the boiling point, they may be boiled in water at the time of an operation in order to sterilize their outside.

Some sutures are labelled "non-boilable." These have been sterilized by heat, and then placed in a tubing fluid of 95 per cent alcohol, the presence of the 5 per cent of water giving extreme flexibility to the catgut. However, a surgeon may make the ordinary suture flexible by immersing it in sterile water for a few seconds.

It may be desirable to impregnate a suture with an antiseptic in order to produce an antiseptic action around the suture in the tissues. Iodine was formerly used, but it tended to weaken the suture. Double iodide of potassium and mercury does not injure the suture material. It will stand boiling, and is even more germicidal than iodine.

White silk and linen have the great disadvantage of being almost completely insoluble in the body, plain catgut is sometimes too soluble, and does not last throughout the entire period of the healing process. Methods have therefore been developed to make the sutures more resistant to the digestive action of the serum of the body, and yet remain flexible and absorbable. The ordinary process is that called chromicizing, and is similar to that used in tanning leather by the chrome method. The process may be applied with accuracy, so that the tanning process may be carried to any stage. A mild stage of tanning will produce a suture whose strength in the tissues will remain unimpaired for ten days, while a more complete tanning will cause the suture to last for forty days. Chromicized sutures are usually classed as 10, or 20, or 40 day sutures, according to the number of days their strength will remain unimpaired in the tissues.

The chromic acid and chromates which are

used in tanning sutures are harmful to the tissues, and therefore it is necessary to remove them from the sutures.

Chromicized sutures are sterilized in the same way as those of plain catgut. They may also be impregnated with germicidal chemicals.

The tendons of animals were among the earliest of suture materials. Those of the tail of the rat were once extensively used for fine suturing, but at present the principal tendons used are those from the hind legs of the kangaroo—a jumping animal whose tendons are long. The crude tendons torn from the legs are in the market in bales of promiscuous lengths and sizes. Apparently the only use for the tendons is that for sutures.

The process of preparing kangaroo tendons is similar to that for catgut. They are assorted for lengths and sizes, and are cleansed and dehydrated, and finally sterilized by heat. They may also be chromicized.

Silkworm gut is made from the silkworms that are ready to spin their cocoons. The worm is killed and steeped in acetic acid so that its flesh will separate from the gland which secretes the silk. The gland is then drawn out to a length of a foot or more, and its ends are twisted around pegs in a board and left to harden and dry. Since the strand is firm and smooth, boiling in water is sufficient to sterilize it.

A common size of silkworm gut sutures is number 0, and is about one-third of a millimeter in diameter, but other sizes are also made.

Horsehair is also frequently used for superficial sutures. The old fashioned way of its preparation was by simple boiling, but since it is likely to be contaminated with spore-bearing bacteria, horsehair sutures are best sterilized at a higher temperature, as in the standard method of preparing catgut.

The preparation of sutures is an example of the essential service rendered to the medical profession by manufacturers. Older surgeons will recall the tedious process of preparing the sutures for operation—the reeling of the catgut on spools, and its sterilization in boiling alcohol, with the frequent softening and exasperating breaking during the operation. But in these days the surgeon buys every kind of suture already prepared for use, and even threaded in a needle, if he wishes. He knows that, when infection occurs in a wound, his sutures are not to blame if he has taken them from the original packages put up by the manufacturer.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers.

**CLINICAL PHYSIOLOGY (A Symptom Analysis) IN RELATION TO MODERN DIAGNOSIS AND TREATMENT** A text for Practitioners and Senior Students of Medicine By ROBERT JOHN STEWART McDOWELL, D.Sc., M.B. With an introduction by W. D. Halliburton, LL.D., F.R.C.P. Octavo of 383 pages illustrated New York, D. Appleton and Company, 1927

**METHODS AND PROBLEMS OF MEDICAL EDUCATION** Sixth Series Quarto of 275 pages, illustrated. Seventh Series Quarto of 104 pages, illustrated New York, N.Y., Division of Medical Education of The Rockefeller Foundation, 1927

**MEDICAL CLINICS OF NORTH AMERICA** Vol 10 No 6 May 1927 (Heart Number) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

**TEXT-BOOK OF BACTERIOLOGY** By WILLIAM W. FORD M.D. Octavo of 1069 pages, with 186 illustrations Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$8.50

**COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION** Volume XVIII, 1926 Octavo of 1329 pages, with 386 illustrations Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$13.00

**THE AMERICAN ILLUSTRATED MEDICAL DICTIONARY** A New and Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, etc., with the pronunciation, derivation and definition. By W. A. NEWMAN DORLAND, A.M., M.D. 14th Edition, revised and enlarged Octavo of 1388 pages, illustrated Philadelphia and London W. B. Saunders Company, 1927 Flexible binding Plain \$7.00 net, Thumb Index \$7.50 net

**A TEXT-BOOK OF PATHOLOGY** By ALFRED STENGEL, M.D., and HERBERT FOX, M.D. 8th Edition, reset. Octavo of 1138 pages with 552 illustrations Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$10.00

**HYPOTENSION** By ALFRED FRIEDLANDER. Octavo of 193 pages Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$2.50 (Medicine Monographs, Volume XIII)

**THE HUMAN BODY IN PICTURES** A Visual Text of Anatomy, Physiology and Embryology by JACOB SARNOFF M.D. Octavo of 120 pages, illustrated Brooklyn, N.Y., Physicians and Surgeons Book Company, (1927) Cloth, \$2.50

**LIPPINCOTT'S POCKET FORMULARY** By GEORGE E. REHBERGER, M.D. Narrow octavo Philadelphia and London, J. B. Lippincott Company, (1927) Cloth, \$3.50

**DIE MORPHIN-ERRANKUNGEN** VON DR. BENNO HAHN, Octavo of 166 pages Heidelberg Dr. Herbert Grossberger, (1927) Paper, Marks 6.80

**INTERNATIONAL CLINICS** Edited by HENRY W. CATTELL, A.M., M.D. Thirty-seventh Series Volume II Octavo of 308 pages illustrated Philadelphia and London J. B. Lippincott Company, 1927

**STANDARD METHODS OF THE DIVISION OF LABORATORIES AND RESEARCH OF THE NEW YORK STATE DEPARTMENT OF HEALTH** AUGUSTUS B. WADSWORTH, M.D., Director Octavo of 704 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$7.50

**DISEASES OF THE NEWBORN** A Textbook for Students and Practitioners By JAMES BURNET, M.A., M.D. 12mo of 275 pages London and New York, Oxford University Press, 1927 Cloth, \$1.85 (Oxford Medical Publications)

**KER'S MANUAL OF FEVERS** Revised by CLAUDE RUNDLE, O.B.E., M.D. 3rd Edition. 12mo of 346 pages, illustrated London and New York, Oxford University Press, 1927 Cloth, \$3.75 (Oxford Medical Publications)

**THE THOMAS SPLINT AND ITS MODIFICATIONS IN THE TREATMENT OF FRACTURES** By MEURICE SINCLAIR, C.M.G., M.B., Ch.B. Octavo of 168 pages, illustrated. London and New York, Oxford University Press, 1927 Cloth, \$4.50 (Oxford Medical Publications)

**NORMAL MIDWIFERY FOR MIDWIVES AND NURSES** By G. W. THEOBALD, B.A., M.D. Octavo of 258 pages, illustrated London and New York, Oxford University Press, 1927 Cloth, \$3.15 (Oxford Medical Publications)

**THERAPEUTIC MALARIA** By G. DE M. RUDOLF M.R.C.S., L.R.C.P. Octavo of 223 pages, illustrated London and New York, Oxford University Press, 1927 Cloth, \$3.85 (Oxford Medical Publications)

**A TEXT-BOOK OF PSYCHIATRY FOR STUDENTS AND PRACTITIONERS** By D. K. HENDERSON, M.D., and R. D. GILLESPIE M.D. Octavo of 520 pages London and New York, Oxford University Press, 1927 Cloth, \$5.50 (Oxford Medical Publications)

**MEDICAL CLINICS OF NORTH AMERICA** Vol 11, No 1 July, 1927 (Chicago Number) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net

**DIAGNOSIS AND TREATMENT OF DISEASES OF THE STOMACH** With an Introduction to Practical Gastro-Enterology By MARTIN E. REHFUSS, M.D. Octavo of 1236 pages, illustrated Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$12.00

**THE ANATOMY OF THE NERVOUS SYSTEM** From the Standpoint of Development and System By STEPHEN WALTER RANSON, M.D. 3rd Edition, revised. Octavo of 425 pages, with 284 illustrations Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$6.50

**THE FOUNDATIONS OF NUTRITION** By MARY SWARTZ ROSE, Ph.D. 12mo of 501 pages illustrated New York, The Macmillan Company, 1927

**MENTAL HANDICAPS IN GOLF** By THEO B. HYSLOP, M.D. With forewords by Rolf Creasy and John Henry Taylor 16mo of 111 pages Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$1.50

## THE MALTHUSIAN DOCTRINE

Is an increase in population always a blessing? Does not war, famine, and pestilence tend to strengthen the race by killing off the weaklings? On the other hand, does not medical science tend to produce a race of degenerates by preserving the sickly and those unfit to endure the stress of life?

These are old questions that were discussed by Thomas R Malthus, a meek and gentle Englishman, a rural curate and professor of history who, in 1804, published a book on population after much travel and research throughout Europe. The statesmen of his day were genuinely alarmed over the rapid increase of population that had taken place throughout Europe until the problem of feeding the people in the larger cities was becoming acute. Since there was no prospect of cultivating more land or of transporting food rapidly for long distances, an increase in population seemed to threaten disaster to the race. The alternatives were either more food or fewer people.

Those were the days of belief in the divine rights of kings and the special privileges of the highly born. Purple, and fine linen, and sumptuous fare were for the nobility. Give the peasants more comfort and vigor, and they will soon become so numerous that they will die of starvation. This had been the accepted doctrine for centuries. Thomas Malthus was too good a Christian to propose man-made war in order to reduce the population, but famine and pestilence were beyond the power of man to control, and were the divinely ordained agents for bringing ultimate happiness to the people.

War has always been an accepted solution of the problem of food supply. If a people lacked food, they went out and took it from neighboring tribes or nations. Eighteen hundred years before Malthus, the people of Helvetia, some 300,000 in number, found the boundaries of Switzerland too narrow for their existence, and so they sought to take the fields away from their next door neighbors, the Gauls. But Caesar drove them home, doubtless decreased in number temporarily, but Switzerland now supports three million people with ease. Caesar taught the Gauls how to make their lands produce double and triple their former yield. He found the people living in villages, between which five miles of ground were unoccupied because the villagers quarrelled over it. "Stop fighting, and till all your land," were the orders of Caesar which

quickly settled the problem of over-population in Gaul.

A hundred and twenty-five years after the death of Malthus the question of over-population is still acute, but his remedies are no longer considered proper. Wars are outlawed, famines are averted by railroads and steamboats, and pestilences are prevented by medical science. But Caesar's remedies of hard work and good will are more potent than ever. The doctors will supply the vigor for doing hard work, and the ministers of the Gospel will supply the good will, and between the two, human life will be increasingly pleasant.

These homiletic thoughts are suggested by an editorial in the *New York Herald Tribune* of August 22, which says, in discussing an article by Professor E. A. Ross in the August *Century* magazine.

"The white race is responsible for increasing not only its own numbers but the numbers of the browns and the blacks. The astonishing increases of world population in the last generation have not been due, Professor Ross reminds us, to any great rise in the rate of births, nor even in the main to the elimination of famine. The chief cause has been sanitation, operating to reduce the death rate. Sanitation is an invention of the whites. Recently we have made it world-wide, conquering the diseases of other climes and other races, as we had already conquered our own. The result is that these other races are expanding like the gas out of a balloon. Already they begin to press upon their own food resources. Presently they will press upon ours.

"With all good will in the world toward our racial companions on this planet, there is no gainsaying the fact that living is a competitive business. An unchecked increase of any one race cannot but lead in the end to the desire, if not the intention, of absorbing the resources of some other race. It is unthinkable that we who have invented the sanitary procedures for the rest of the world should now withdraw them merely because we fear that they are too effective for our own safety.

"To safeguard our humanity is more important even than to save our lives. There must be another way out—a way less cruel for everybody. What is most needed now is study. Disaster in any event is remote. There is plenty of time to digest these awkward facts about increasing racial populations and to decide what need be done."

**DISEASES OF THE DIGESTIVE ORGANS** With Special Reference to their Diagnosis and Treatment. By CHARLES D AARON, Sc.D., M.D. 4th Edition, thoroughly revised. Octavo of 927 pages, illustrated Philadelphia, Lea and Febiger, 1927 Cloth, \$11.00

In this fourth edition, Aaron has added much valuable new material, but unfortunately, as is the case with most revisions, has not deleted enough of the old and more or less obsolete material. The book is now practically an encyclopedia of gastroenterology, and can be used as a reliable reference work on the history and practice of this special field.

The new illustrations of roentgenographic findings in the various conditions in which X-ray diagnosis is of help are among the best in any text book.

The chapters on diet are most sensible—instead of diet tables there is a comprehensive discussion of the principles involved, so that the reader may make up his own diets to fit a given case, in accordance with these principles.

A good chapter on diseases of the mouth is most helpful, as are the chapters on rectal diseases.

On the whole the book merits a place in any complete medical library.

**THE PSYCHOLOGY OF MENTAL DISORDERS** By ABRAHAM MYERSON, M.D. 12mo of 135 pages New York, The Macmillan Company, 1927 Cloth, \$1.40

The public possesses a greater fund of misinformation concerning mental disturbances than on almost any other medical subject. Therefore, this little book, coming from an authoritative source, should prove of definite service. As the author expresses it, it "seeks to stimulate intelligent non-professional interest in a serious subject, and thus make possible for society to grapple more resolutely with the problem of mental disease."

The book is written in such a delightful style—and with such a commonsense appreciation of relative values—that it cannot fail to hold the reader's interest. And much of its contents will prove enlightening to the physician as well as the lay reader.

FREDERIC DAMRAU

**THE TREATMENT OF CHRONIC ARTHRITIS AND RHEUMATISM** By H WARREN CROWE, M.D., B.Ch. Octavo of 196 pages, illustrated. London and New York, Oxford University Press, 1926 Cloth, \$2.75 (Oxford Medical Publications)

The author reports such wonderful results in the treatment of the above mentioned conditions that one is surprised that the results have not been obtained by many others and universally used. When a method of treatment is advocated by an individual with brilliant results and others do not get the same results, we feel that something is at fault with our technique or our knowledge. This volume is carefully presented, is clearly expressed, is instructive, contains many illustrative case histories and shows results obtained by the author. It will well repay a careful study by anyone who may have to treat these cases, so difficult to treat, and obtain lasting benefit. If vaccine therapy by a master can cure these patients, much illness can be prevented.

HENRY M MOSES

**A MANUAL IN PRELIMINARY DIETETICS** By MAUDE A PERRY, B.Sc. 16mo of 146 pages St. Louis, The C.V. Mosby Company, 1926 Cloth, \$1.25

This manual has been prepared for "the instruction of nurses in preliminary dietetics." It is essentially for nurses, and is elemental in character. The work is arranged in fifteen lessons and each chapter is accompanied by a summary which indicates very definitely what is to be learned. The author is the director of Dietetics in the Montreal General Hospital, and she handles her subject with the firm hand of a seasoned veteran. Many of the older nurses who did not have the benefit of a real

course in dietetics during their years of training will find much of value in this small volume. L C J

**OBSTETRICS FOR NURSES** By JOSEPH B DE LEE, A.M., M.D. 8th Edition, revised. 12mo of 635 pages, with 266 illustrations Philadelphia and London, W.B. Saunders Company, 1927 Cloth, \$3.00

Doctor De Lee is so well known to the medical profession, as an author, as a teacher, and as a man of wide clinical experience, that he needs no introduction.

This is the eighth edition of *Obstetrics for Nurses*, which first appeared in 1904. When a text book has reached the eighth edition, and when it has been in use as a standard for more than twenty years, it compels consideration for itself.

In this edition, as in former editions of the book, the author has been careful not to reflect all the changes and controversies which agitate the field of obstetrics, but rather to bring before the student nurses, only well established facts and practices.

The text book has been changed but little from that of former editions. Several old illustrations have been omitted, and new ones added. Some new subjects have been added, such as—the iodine and mercurochrome preparation of the parturient for labor.

Gwathmey's synergistic obstetric analgesia, and identification of new born babies.

Part I considers the anatomy and physiology of the female reproductive system, in its relation to the pregnant woman, and it also includes a chapter on the hygiene of pregnancy.

In Part II the care of the patient during labor and the puerperium, as well as the care of the child, are carefully set forth.

Part III is devoted to the pathology of pregnancy and puerperium, as well as to the pathology of the new born child.

The Appendix contains much valuable information in regard to home nursing in obstetrics. Methods of sterilization of hands and utensils and a thorough consideration of various diets, are also covered in this chapter.

The chapter on infant feeding, which has been revised by Dr D B Witt, of the Pediatric Department of the Chicago Lying-In-Hospital, is clear and concise.

The book is comprehensive, and covers the field in great detail. The language is simple and easily within the grasp of the student mind.

WM SIDNEY SMITH

**ACTIONS AND USES OF THE SALICYLATES AND CINCHOPHEN IN MEDICINE** By P J HANZLIK, M.D. Octavo of 200 pages Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$3.50 (Medicine Monographs, Vol IX.)

In view of the fact that rheumatic fever is third in the list of the first sixteen diseases disabling the adult sick in the United States this very comprehensive and authoritative discussion should prove of much interest. In addition, it should settle many mooted questions regarding the actions of salicylates and, incidentally, cause a discard of much of the manufacturers' literature regarding the superiority of this or that preparation.

Briefly, the conclusions of Dr Hanzlik are about as follows:

- 1 The actions producing the characteristic relief are antipyretic and analgesic, together with an increased capillary permeability (diuresis).
- 2 That the sodium salt is the most efficient form.
- 3 That an equal dosage of sodium bicarbonate modifies the gastric irritation.
- 4 That the dosage should be one gram hourly to the point of salicylism.
- 5 That the action of cinchophen is about the same as the salicyl compounds.
- 6 That the intravenous route is not superior to the oral.
- 7 That the salicylates are useless in chronic cases.

M F DE L

# BOOK REVIEWS

**LISTER, AS I KNEW HIM** By JOHN RUDD LEESON, M.D. Octavo of 212 pages New York, William Wood and Company, 1927 Cloth, \$3 50

Every physician should read this book. He should read it for the rare pleasure to be derived from a perusal of its pages. He should read it for the story of the man who made present-day operations a commonplace. He should read it to get fixed in his mind the true and authentic history of one of the great men in the history of medicine.

The first chapter Before Lister should be done in brochure form and broadcasted to all doctors throughout the world. This should be followed by the chapter entitled Description of an Operation.

The book tells in its early pages of the frightful mortality from surgical procedures. Especially interesting is the story of a young man about to be married who consulted one of the well known surgeons of that day. He said his bride-to-be objected to his crooked nose. The surgeon straightened the septum. In five days the patient was on the post-mortem table. This was no unusual happening.

It will surprise most readers to learn that while Lister was making history destined to travel down the years to infinity, and while his clinic was crowded by well known doctors from America, Europe, the Orient, and Africa never did the British doctors, especially of Edinburgh and men on other divisions of Lister's hospital honor him by attending his clinics. He was not a prophet in his own country.

The author worked with Lister. He is one of the few still living who worked with this great man. And so such a delightful, simply written authentic volume about Lister by one who knew and worked with him is sure to be read and reread by physicians the world over.

We recommend most highly to all who read these lines this book.

T S W

**THE LIFE AND WORK OF SIR PATRICK MANSON** By PHILIP H. MANSON-BAHR, D.S.O., M.D., and A. ALCOCK, C.I.E., LL.D. Octavo of 273 pages New York, William Wood and Company, 1927 Cloth, \$5 50

Except to those interested in Tropical Medicine and certain phases of medical history probably few know about Sir Patrick Manson. And yet he was one of the real and true pioneers in medicine. His work in Tropical Medicine, especially as regards Malaria were beacon lights pointing the way.

The book is delightfully written, interesting, and well worth while. To anyone interested in the lives of real Doctors of Medicine, their struggles, work and final achievements, this volume is earnestly recommended.

T S W

**PYGMALION OR THE DOCTOR OF THE FUTURE** By R. M. WILSON M.B., Ch.B. New York, E. P. Dutton & Company, 1926

This is one of the today and tomorrow series in which the writer attempts to tell what the doctor of the future will, and what he will be able to accomplish in the way of cures. The author examines and discusses in detail the belief, a symptom is a sign of disease. His conclusion is that symptoms are signs not of reaction to disease, but of altered reaction to life occasioned by the presence of disease. He points out the value of this new discovery and relates some of the remarkable cures that have been effected by means of it especially when applied to diagnosis.

F B D

**LECTURES ON INTERNAL MEDICINE.** (Delivered in the United States, 1926) By KNUD FABER, M.D. Octavo of 147 pages, illustrated New York, Paul B. Hoeber, Inc., 1927 Cloth, \$3 00

There are four lectures in this volume, namely "The Etiology and Pathogenesis of Achylia Gastrica," "The Intestinal Origin of Pernicious Anemia," "Benign Glycosuria" and an "Historical Outline of Medical Therapy."

Chronic Achylia is believed by the author to be due to an exogenous cause produced by external factors acting on the stomach either by direct irritation of the mucous membrane or through the blood circulation by a toxic action on the gastric parenchyma. Gastritis with achylia should be pictured not as a superficial inflammation but as a disease of the glandular parenchyma analogous with nephritis or hepatitis.

Faber believes that the central fact in the pathogenesis of pernicious anemia is its origin in intestinal intoxication. The achylia generally present is believed to be primary to the anemia and in some way contributory to its occurrence.

In the lecture on benign glycosuria the author gives the usual figures for a normal blood sugar threshold as 0.16 to 0.18%. In true renal glycosuria the threshold is found to be 0.05 to 0.12% or lower and in the renal alimentary or cyclic glycosuria it is generally 0.12 to 0.15%. In the former type sugar may be present in the urine at any time and in the latter is found only after meals and not in the morning or night. The author believes that in the same individual the position of the threshold is constant during the lifetime and that this is true both of benign glycosuria and true diabetes. If the fasting blood sugar is abnormally high the diagnosis of true diabetes should be made.

W. E. McCOLLUM

**THE SHIP-SURGEON'S HANDBOOK** By A. VAVASOUR ELDER. 3rd Edition. 12mo of 523 pages New York, William Wood and Company, 1927 Cloth, \$3 75

In a narrowed field of work, a most interesting outline pertaining to the medical duties aboard ship, not only on the Atlantic service but also on the high seas in general, has been brought up to date in a most pleasing volume. The author, after years of travel in the capacity of ship surgeon, gives not only his own experiences but that of his fellow workers. To the young physician about to make a trip or two following his hospital career, valuable information relative to his duties are clearly detailed and enables him to comply with all regulations aboard ship as well as entering and leaving various countries which have detailed paper requirements. As a book of information to the casual reader, much interest is aroused by the easy approach and pleasing manner in the presentation of the subject.

E. W. S.

**HIGH BLOOD PRESSURE ITS VARIATIONS AND CONTROL.** A Manual for Practitioners. By J. F. HALLS DALLY, M.A., M.D. 2nd Edition. Octavo of 196 pages, illustrated New York, William Wood and Company, 1926 Cloth, \$4 00

The second edition of this excellent work on blood pressure is the result of the demand for some complete presentation of the subject. This edition explains in detail many of the less understood facts of the value of blood pressure readings, together with the causes of various pressure readings. The methods of obtaining correct readings clearly illustrated. Methods of treatment for high pressure are given. This is an instructive, authoritative, up-to-date work on the subject of high blood pressure.

# OUR NEIGHBORS

## CHIROPRACTORS SEEK A NEW LAW IN OHIO

The October first issue of the Ohio State Medical *Journal* devotes considerable space to a proposed law which would "permit chiropractors to treat infectious, contagious and venereal diseases, to sign birth and death certificates, practice in hospitals, state institutions and under workmen's compensation law"

The bill is to be submitted to the voters at the general election by the process of the initiative after "twelve similar bills have been defeated by the legislature in recent years. The proposed bill received only 31 votes out of 136 members of the House of Representatives on March 15"

The Constitution of Ohio permits the Governor to appoint committees to prepare explanations and arguments "for and against" an initiated bill. The arguments are limited to 300 words each and are to be circulated by the Secretary of State. The committee to present the arguments against the bill consists of "Bleeker Marquette, Secretary, Cincinnati Public Health Federation, Cincinnati, V. Lota Lorimer, Lakewood, President, Ohio State Association of Graduate Nurses, and William C. Wendt, member Ohio General Assembly, Columbus"

The argument prepared by the committee is as follows: "Vote 'NO' on the initiated bill. Do not grant chiropractors (with eighteen months schooling) all legal rights and duties of regular physicians (with six years training) by permitting chiropractors to treat infectious, contagious and venereal diseases, to sign birth and death certificates, practice in hospitals, state institutions and under workmen's compensation law"

"A single 'adjustment' method, (chiropractic) for appendicitis, diphtheria, typhoid, syphilis, smallpox, diabetes, cancer, Bright's disease, rabies and all types of physical and mental ailments is dangerous"

"Medical science has proved the value of antitoxins, vaccination, insulin, salvarsan, anesthetics, antidotes for poisons, and surgery. All those are denied by chiropractic theory"

"Should chiropractors who discredit bacteriology, immunization and preventive medicine, be permitted to treat infantile paralysis, tetanus,

meningitis, diphtheria, typhoid fever and scarlet fever?"

"At present, chiropractors are licensed as 'limited practitioners' after examination by State Medical Board in basic branches, anatomy, physiology, chemistry, pathology and diagnosis, and by an examining committee of licensed chiropractors appointed by the board. Four hundred are so licensed, 160 in the past four years. Such 'limited practitioners' are not now and should not be permitted to treat infectious, contagious and venereal diseases, practice obstetrics, use drugs or surgery or sign death certificates"

"Would you accept chiropractic for hog cholera, glanders or bovine tuberculosis?"

"Courts have repeatedly declared the present license laws and administration correct and just—proper protection against unscrupulous and unqualified practitioners. Chiropractors seek 'special privilege' under pleas for 'fair play'."

"Twelve similar bills have been defeated by the legislature in recent years. The proposed bill received only 31 votes out of 136 members of the House of Representatives on March 15"

"If in doubt about this dangerous proposal ask your health commissioner, physician or hospital authorities. For protection of public health, vote 'No'."

Editorially the *Journal* says: "Spectacular publicity stunts and campaigns such as the chiropractic 'Go-to-Jail' campaigns have characterized many efforts to secure special privilege. These have failed to impress the public apparently, for they have been abandoned"

"Now the tactics have been altered. The million and more electors of Ohio will pass upon the proposal in November. The theory back of this is rather clear, in other words, it may be easier to fool and hoodwink a great mass of people than a few who have opportunity to investigate the misleading claims and fallacious statements"

"Community health in Ohio is confronted with a real crisis. Every citizen should use his influence toward defeating the chiropractic proposal as a means of shielding his fellow townsmen, his family, friends and relatives from the possibilities of a complete destruction of public health safeguards"

(Continued from page 1162)

San Antonio, Texas Col Crimmins described the venom as follows

The venom is a thick, amber colored liquid, neutral or slightly acid, and has a specific gravity of 1.030 to 1.050. It is soluble in a normal salt solution, and generally, in distilled water. When dried, it forms clear yellow crystals, in elongated laminae. It is composed of the following: (1) A powerful fibrin ferment, (2) an antifibrin ferment which attacks the coagulating element of the blood, (3) a proteolytic ferment which dissolves the muscles, (4) cytolsins, which dissolve the red and white blood cells, endothelial and nerve cells, (5) an antibacteriocidal substance of the nature of an anticomplement, (6) neurotoxins, with a special affinity for nerve cells, (7) a neurotoxin with an affinity for the nerve terminals of the muscles, and (8) a substance which reinforces the cardiac tonus and causes the heart to stop in systole, in some cases.

The venom is largely composed of an albuminoid, and is chemically closely related to the normal constituents of the blood. Therefore, no chemical antidote can be administered into the circulation, which would destroy the venom, that would not, at the same time, destroy the blood. After the venom has reached the circulation, we have to rely upon an antivenom serum to neutralize it. Snake venom is extremely irritating in addition to its slow absorption. It is diluted by the lymph in the intercellular tissues, and if we can abstract it from where it is being absorbed, we can decrease the pain and by eliminating a part of the venom, increase the chances of recovery. If a series of small punctures or cross cuts are made along the periphery of the swelling, the bloody venomized serum will ooze out through the openings, which can be further accelerated by using a small suction pump, similar to a breast pump, with a circular nozzle for flat surfaces, and a narrow one for use on the fingers and toes. A rubber tourniquet should be applied proximal to the wound, to delay absorption until other first aid measures are instituted. The tourniquet should be removed about every twenty minutes, for a period of about ten seconds, to re-establish the circulation and to prevent gangrene. A tourniquet that has been applied too tightly may cause the venom to be carried deeper into the tissues and between the bones, where the blood vessels are not compressed, and where it is impossible to use local treatment.

The prognosis of snake bites in man is affected as follows

(A) Factors in which the snake is concerned  
(1) Blind strikes which are made with the mouth closed, due to imperfect vision. This is

(Continued on page 1165, adv. rev.)

(Continued from page 1164, adv viv)

caused by the thick skin which covers the eyes for a week before shedding (2) Miscalculation of the striking distance because of imperfect daylight vision (3) A failure to close the lower jaw, which prevents the excretory muscles from being brought into full play (4) Fangs not sufficiently elevated (5) Inaccurate approximation of the venom papillae, which is the case when new fangs are about to replace the old ones (6) Diminished venom due to (a) Feeding, (b) hibernation, (c) aestivation, (d) captivity, and (e) extreme youth or old age

(B) Factors in which the animal or person bitten is concerned (1) Interposition of hair or clothing, thereby preventing a proper lodgment of the fangs (2) Movement of the animal or person attacked, which causes an imperfect lodgment of the fangs or a miscalculation of the striking distance, by the snake (3) The wound occurring in a very fat area, where the circulation is sluggish (4) The wound occurring in an area having little connective tissue as on the finger, toe or shin

Dr Jackson described a series of experiments in which known amounts of venom were injected into dogs. He also demonstrated the existence of venom in the serum which exuded from cuts over the swollen area around the bite. He further showed that the venom could be extracted by persistent suction, and that the permanganate treatment was useless.

The following extracts are taken from Dr Jackson's paper

"A weak solution of potassium permanganate in a 1 3000 solution, will not oxidize a lethal dose of venom, even in a test tube. A 1 300 solution, and as strong as 1 per cent will not oxidize venom that has been injected into animal tissue. Even pure crystals of the drug showed no beneficial results in treatment, and it is our opinion after having observed recently a fatal case of rattlesnake bite in a child that injection of a strong solution of potassium permanganate charred the tissues and prevented the normal outpouring of lymph which helps to wash out some of the poison and, in our opinion, this injection of permanganate in this manner contributed to this child's death.

"To our surprise, and contrary to the opinion of the supposed best authorities on the subject, we found that rattlesnake venom can be easily extracted mechanically. The text-books have insisted that it could not be, evidently, erroneously based on experiments conducted with cobra venom many years ago. Our grandfathers, who resorted to cupping, and the ignorant Indian who sucked the wound with his mouth, were doing much more to save the

Horlick . . . Racine

(Continued from page 1165, adv xv)

patient, than our scientific fellow with his "hypo" of potassium permanganate

"We have learned a great deal from a study of over 60 autopsies performed on dogs that had died from the effect of snake venom

"It has been generally accepted that venom was rapidly absorbed through the venous system and did not remain over a few minutes in the neighborhood of the bite. We have found that venom when injected into a dog's thigh, slowly spreads through the intracellular lymph spaces and finally finds its way into the inguinal lymph glands, where it produces a violent hyperemia, followed by death and necrosis of these glands. It spreads from this region to the glands located at the bifurcation of the abdominal aorta and up this chain to glands situated near the diaphragm

"Logical treatment, which consists of free incision wherever there is a swelling, for in this there is a concentrated venom in solution, and the nearer the swelling to the bite, the greater the concentration. This tissue should be incised freely and all of the blood and lymph possible extracted, for it contains the substance which will kill the patient, if allowed to remain in the tissues and become diluted sufficiently to be absorbed. Where there is swelling, there is venom being prepared by dilution for absorption. We have found venom in the area of a bite, 24 hours after its injection

"It has been our experience that sufficient incisions are not made in most cases. Small cross cut incisions about one-eighth of an inch wide and one-fourth of an inch deep give the best result. A ring of these should be made at the top of the swelling and in nests of seven or eight over the areas where the greatest swelling is found. These can be continued up the arm, or over the chest if the swelling approaches these areas. These punctures or cuts should not be confined to the immediate site of injury. The most dangerous fluid is farthest away from the wound. Its absorption must be prevented as it is the source of the systemic poisoning. (This poison may be a new proteolytic substance formed from the action of the venom on tissues, as has been suggested by W A Bevan. However, it is most likely diluted venom, and is a fluid of fatal possibilities)

"I wish to stress the proper method of treatment in cases of rattlesnake bite. A tourniquet should be applied to increase the venous congestion and assist in washing out the poison. A cross cut incision one-fourth by one-fourth inches should be made over each fang mark, or preferably to connect the two fang punctures. Suction should be applied for at least one-half hour. If this is done within an

(Continued on page 1167, adv xvi)

(Continued from page 1166 ad. xvi)

hour from the time a person is bitten very little additional treatment is necessary, however, if the swelling has increased up the arm or leg novocain should be injected, completely encircling the limb above the proximal edge of the swelling. A double line of small cross cuts, about one-eighth of an inch deep and across should be made. They should be about one inch apart, and encircle the limb. Suction should then be used for one-half hour. If there is a pocket or some area more swollen than another, a nest of punctures should be made over this area and suction applied. A large quantity of bloody serum containing venom can be withdrawn. New punctures should be made every few hours and suction repeated for one-half hour. This treatment should be continued for the first eight or ten hours after the patient has reached the hospital. If the swelling does not decrease, the entire process should be repeated. The puncture wounds will continue to leak the diluted venom out of the tissues. Practically all the cases under my observation, which had been treated by suction, were under rather than over-treated, so when in doubt the number of punctures, and the amount of suction should be doubled.

"I wish to again stress the importance of colonic irrigations of salt and soda solutions. They should be repeated about every four hours. Blood transfusions are also essential in desperately ill patients who have already had a great many red blood cells destroyed. The affected limb should be kept wrapped in a hot solution of magnesium sulphate. The hot solution of magnesium sulphate or a sodium citrate solution will increase the weeping of these wounds. We have seen no sloughs in the cases of rattlesnake bites which were treated with suction."

Antivenin, a serum for snake bites, is supplied by the H. K. Mulford Company, Philadelphia, Pa.

patient, than our scientific fellow with his "hypo" of potassium permanganate

"We have learned a great deal from a study of over 60 autopsies performed on dogs that had died from the effect of snake venom

"It has been generally accepted that venom was rapidly absorbed through the venous system and did not remain over a few minutes in the neighborhood of the bite. We have found that venom when injected into a dog's thigh, slowly spreads through the intracellular lymph spaces and finally finds its way into the inguinal lymph glands, where it produces a violent hyperemia, followed by death and necrosis of these glands. It spreads from this region to the glands located at the bifurcation of the abdominal aorta and up this chain to glands situated near the diaphragm

"Logical treatment, which consists of free incision wherever there is a swelling, for in this there is a concentrated venom in solution, and the nearer the swelling to the bite, the greater the concentration. This tissue should be incised freely and all of the blood and lymph possible extracted, for it contains the substance which will kill the patient, if allowed to remain in the tissues and become diluted sufficiently to be absorbed. Where there is swelling, there is venom being prepared by dilution for absorption. We have found venom in the area of a bite, 24 hours after its injection

"It has been our experience that sufficient incisions are not made in most cases. Small cross cut incisions about one-eighth of an inch wide and one-fourth of an inch deep give the best result. (Continued from page 1167, adv xvi)

medicine, that in all endeavors it first becomes necessary to educate the physician—to advise him how, when, and where things should be done. He should be assuming leadership, but instead too often he must be dragged along. Too frequently the public is far better instructed upon matters of preventive medicine, because the physician will not keep abreast of the publicity that is being continually given to the community, and it is regrettable that when patients talk these matters over with their physician, the latter seems to assume the attitude, 'What is it all about?'

"We must realize that one of our greatest problems is the education of the public in medical matters, and that to do so costs money. The county societies must realize their increasing responsibilities to themselves and to the public and the necessity for funds to meet these obligations.

"The discussion of the conference also plainly demonstrated that the physicians of the three States are falling down very badly on periodic health examinations. The public is being thoroughly instructed. The physicians are totally indifferent. The people, consequently, in too many instances are having this examination made by an institute the physician condemns. There is no one to blame but himself. He must realize that he is the basic factor in all matters medical, and he must assume his full responsibility. Unless he does, he fails to fulfill his mission, and it is his financial loss.

"He must be keenly awake to the necessity of periodic health examinations of children of the pre-school age. This is essentially the problem of the attending physician. When the children are in school, various agencies begin to take hold, but much should be done previous to the time they go to school, and this very essential period must be properly consummated by the attending physician.

"The need of diphtheria immunization is most essential, and here again in the pre-school age, especially three to five years of age, is the time when this very important procedure should be done. The physician must advocate the necessity for it, urge its acceptance, and show his willingness to do it. The responsibility is primarily on the shoulders of the physician, more especially in children of the pre-school age. We must realize this. Not only should we urge immunization, but show our willingness to do it."

The supplement to the August issue of the *Journal of the Medical Society of New Jersey* also contains a side light on the Tri-State Conference in the following remarks by Dr. J. B. Morrison, Secretary of the Society, before the annual meeting on June 11.

(Continued on page 1169, adv xiv)

(Continued from page 1168, adv xxiii)

"The reason for continuing this educational campaign is very, very great. It has been brought home to me more forcibly in my conferences with these Tri-State Medical Conferences than in anything else. We have learned in the last two sessions, especially the session in New York, of the enormous activities of social and welfare organizations. As Dr. Green said in his address yesterday, it has become a profession, and many of them enter into those professions with the zealously of a missionary. They are backed up by influential people who give the greater bulk of their time, many of them women, to furthering these social welfare matters, and they are backed up by an enormous appropriation of money. They are here to stay, they are going to spend that money, they are going to do that work and here in New Jersey out of a clear sky they came to the medical profession for some guidance. The medical profession did not originate it. The Health Officer in East Orange and the Antituberculosis League were very, very anxious to get this work over, but they felt they wanted, in justice to the medical profession, to let the medical profession do the leading."

#### THE COMMONWEALTH FUND AID TO HOSPITALS

The Commonwealth Fund, with headquarters at 1 East 57th Street, New York, is one of the great foundations similar to the Milbank Fund. It conducts demonstration along health lines especially in child welfare, but very little publicity follows its work. It has recently taken up the work of aiding rural hospitals.

The *Journal* of the Maine Medical Association for August announced that Farmington, a village of 3200 people in West Central Maine will receive \$14,000.00 from the Commonwealth Fund to cover two-thirds of the cost of a 50-bed community hospital, to serve a community of 30,000 people that are shut off from other hospital facilities. The account says in closing:

"According to the last annual report of the Commonwealth Fund, the Board of Directors, in approving the project for building rural hospitals, had in mind 'the obvious and widespread lack of accessible hospital facilities in general character in rural districts, and the accumulating evidence of the disadvantage of rural communities as compared with urban in the matter of health, as shown in many instances both by their higher morbidity and mortality rates, and the higher proportion of defects among rural school children. These hospitals, strategically located in various sections of the country, it is believed, will in time influence neighboring communities to establish similar facilities out of their own resources, and will help to break down the tradition that the hospital is purely rehabilitative'"

## TEACHING HOSPITALS

Every hospital is a teaching hospital in so far as it affords experience for a doctor. But the doctor who uses the hospital merely as a convenient home for his patients does not gain experience. A doctor must study and reflect on his cases, compare them with one another and with those of other observers, before he really has that experience with which the busy doctor is credited by the people generally.

Physicians have shown a great progress in making use of the educational opportunities which every hospital offers to them. The September issue of the *Rhode Island Medical Journal* discusses the teaching hospital in the following editorial:

"You must realize that this is not a 'teaching hospital.' How often have we heard this offered as a complete and unassailable excuse for inadequate equipment or inefficient methods in a hospital not directly connected with a medical school. And the pity is that the statement is made in all good faith and is usually accepted without question. It might be well, however, to consider carefully whether any hospital can perform its function without being, in a very real sense, a 'teaching hospital'."

"The primary purpose of a hospital is the care of sick patients, and many would say that this is the only purpose. But they forget that the

care of patients involves trained personnel, chiefly doctors and nurses. For years it has been recognized that the training of nurses is a hospital problem, and so we have our hospital training schools doing excellent work in the teaching of nurses. It is harder for us to realize that the hospital must train its doctors. The internship is post-graduate medical work and should be recognized and treated as such. It should involve not only the performance of work without which it would be extremely difficult for us to run our hospitals, but careful and systematic instruction in practical medical and surgical subjects by well-qualified members of the visiting staff. Only in this way can the hospital properly supplement the very sketchy outline which is the best that any medical school can hope to give its students in the formal course, and failure of the hospital at this point means a poorly trained medical personnel with its inevitable effect on the treatment of patients. And this training must also be given to the younger members of the visiting staff to fit them for the more important work which will come to them in the course of years.

"Training of personnel, then, is a matter of vital importance to every hospital, and the institution which is not truly a 'teaching hospital' is not fulfilling its duty to its patients or to the community which it serves."

## FINANCIAL INFORMATION

The doctor is proverbially an easy mark for financial sharps. Not only does he often fail to collect his bills, but he all too frequently invests his surplus with glib salesmen whose principal stock in promises. Northwest Medicine, in the September issue, has this to say about the manner of dealing with a salesman of an uncertain stock:

"This situation could easily be prevented and readily avoided by any physician who would consult his Better Business Bureau, whenever these tempting morsels are dangled before his vision as bait for his consumption. These bureaus exist in most of the large cities, parts of a national organization, established and maintained by the banks and leading commercial houses, whose sole object for existence is investigation and publicity regarding the claims of all concerns offering stock for sale to the public. This information is available for the seeking, without cost on the part of anyone who desires it. If the data concerning a given enterprise are not on file, they will be diligently sought and obtained on short notice. In view of the existence of these bureaus, there is no excuse for a physician to be thus imposed upon and mulcted of his earnings by investments in fraudulent organizations. The next time an eloquent promoter calls at the office, endeavoring to convince you that purchase of stock in certain enterprises will bring returns to comfort and support you in your old age, at once telephone to the Better Business Bureau for information before investing. If the salesman objects to such procedure or grabs his hat and forthwith decamps, it will be at once evident that the proposed inquiry is a profitable one. It, on the other hand, he sits out that investigation, it will be presumptive evidence that there may be virtue in his proposition.

## FUNCTIONAL MEDICINE

Sickness consists in a disturbance of function rather than of structure. In order to know the abnormal, one must know the normal. The foundation on which the practice of medicine rests is a knowledge of the basic sciences, physiology, chemistry and anatomy, and the greatest of these is physiology.

This thought is set forth in the following editorial in the September issue of *Colorado Medicine*—EDITOR'S NOTE

Function is the magic word of modern medicine. It gives the cue to precise diagnosis and successful therapy. It in no way supplants but rather complements the mechanical and anatomical viewpoint which has dominated scientific medicine for the past half century. The objective of the older view was primarily to determine the structural change underlying disease and to attempt to restore thus changed tissue or organ to normal. Upon this solid rock surgery has justly established itself as first among therapeutic procedures. But functional medicine seems now to have its inning. Physiology has come to the aid of pathology in the practice of medicine. It is no longer sufficient to determine an accurate structural change of an organ, but rather the nature and degree of its functional impairment. Likewise our most successful therapeutic efforts are, as a rule, based on a knowledge of function rather than structure. Out of such a concept has sprung the accepted methods of measuring functional impairment of various organs. All too often the underlying structural pathology is a closed book. How different is impaired function! For example an accurate knowledge of limitation of function of the heart, kidneys, pueritis, nervous system, etc., and an adjustment of life within these determined limits renders the detects trifling.

One of the best texts on diagnosis and therapeutics is a modern text book on physiology.

## RAMBLES IN THE FIELD OF GASTRO-INTESTINAL THERAPEUTICS\*

By WALTER A. BASTEDO, M.D., NEW YORK, N Y

"God-like is the physician who is a philosopher"  
—Hippocrates

IN this paper it is my desire to give from my own experiences my answers to some of the questions which arise in the practice of medicine. But in making a personal contribution of this character I desire above all things to avoid a dogmatic attitude, for do we not all know that in the hands of different men what seem to be opposing methods attain apparently equally good results. On the advice of one of our busy New York practitioners I begin my talk on gastro-intestinal therapeutics with some remarks on foods.

**Foods—Milk** Of the really ill there are just two classes of people in the world, those who are natural milk-drinkers, and those who are not. Would that all were of the former class, for milk contains all the elements necessary for growth and maintenance, even to iron for blood building, calcium for bone, phosphorus for brains, protein for muscle and vitamins and salts. Prof Sherman of Columbia urges the use of milk for its calcium if nothing else. It contains practically the same amount as limewater. Moreover in the stomach milk takes up acid and is a soothing application to the stomach wall, and in the bowel it does not readily undergo putrefaction. The fact is, the good milk-drinker makes the doctor's task an easier one.

Of those who apparently are not good milk-drinkers many can be trained to become so, and such training is worth a trial. But there are a number who, try as they will, find that milk invariably sooner or later brings on headache, loss of appetite, gastric discomfort, flatulence or diarrhea. Such cannot be made milk-drinkers. The constipating properties of milk so much heard of are essentially due to the fact that it is not a residue former.

Milk is a liquid food only as it is swallowed, for after it reaches the stomach of normal secretory type milk becomes a solid or semi-solid food, the normal curd in the normal stomach being

rather large and tough. In the highly acid stomach milk may form great hard lumps, while in the stomach that totally lacks gastric juice, the achylic stomach, it does not curd at all but passes to the duodenum in liquid form, there to be curdled by the pancreatic ferments. However, owing to regurgitation of duodenal contents it occasionally curdles in the achylic stomach in tough rubbery masses that pass the pylorus with difficulty, and indeed have caused temporary pyloric obstruction. I have had four such cases.

In normal subjects, not sick ones, Hawk and Rehfuess found that milk was digested with equal readiness whether drunk slowly or gulped, in fact, when it was bolted it had a finer curd and left the stomach more quickly than when it was sipped. In practice, however, one cannot depend on this, and in some cases it is well to have milk *eaten* rather than drunk, i.e., eaten with a spoon like soup.

If thought desirable we may ensure fine curds by boiling the milk, or by using one of the lactic acid milks, or we may abolish the curd altogether by adding to the milk sodium bicarbonate, sodium citrate or limewater or by peptonizing. Twenty minutes peptonization by the warm method is usually sufficient for this. Skim milk makes a tougher curd than whole milk, cream a finer curd. Excluding skim milk it may be said in general that the richer the milk the finer is the curd, but the greater is the delay in evacuation from the stomach. Half and half cream and milk, and especially 40 per cent cream, are decidedly delayed in their evacuation and may result in sour stomach or some other form of indigestion. Boiled milk contains less soluble protein than raw or pasteurized milk but is more readily digested.

It is of interest to note that there is a limit to the digestion of any given substance, even of milk. Harley and Goodbody found that a normal subject on four pints of milk a day lost 218 grams of fat in the feces, on  $4\frac{1}{2}$  pints of milk he lost 295 grams, and on 5 pints he lost 513 grams, i.e., more than twice as much loss of fat on 5 pints as on 4 pints.

**Soured Milks**—There are fashions in therapeutics, and like other fashions soured milks wax

\*Read at the Twenty-eighth Annual Meeting of the Lake Keuka Medical and Surgical Association at Lake Keuka, N Y July 15, 1927

and wane in their use in medicine. In yesterday's fashion plates the most figured souring germ was the *Bacillus Bulgaricus*, in today's it is the *Bacillus acidophilus*, and writers now attribute to it the marvelous virtues formerly ascribed to the *Bacillus Bulgaricus*. The *acidophilus* germ was studied carefully 25 years ago by Herter, and discovered by him to be impractical as a therapeutic agent for the reason that it does not live in the bowel except under ideal conditions of feeding with milk and sugar of milk. Even then it is not a vigorously growing germ and in its dying condition can hardly have any great therapeutic value. It is very easily overwhelmed by the colon bacillus which multiplies 60 times as rapidly. Rettger and Cheplin, two of its greatest advocates though not practicing physicians, state that the *acidophilus* flora persists so long as lactose or dextrin diets are continued, otherwise not over 5 or 6 days, and many investigators report that there are scarcely any patients who show *acidophilus* bacilli in a vigorous living condition for as much as two weeks after a return to normal diet.

To affect the frequency of bowel movements in constipated insane subjects, Kopeloff found it necessary to give daily not less than 1000 c.c. of *acidophilus* milk with 300 grams of sugar of milk, and in some instances as much as 1500 c.c. of the milk and 400 grams or 13 ounces (nearly a pound) of sugar of milk per diem. And in a number of the cases these large amounts did not abolish the intestinal putrefaction. After a *bacillus acidophilus* culture, not *acidophilus* milk (Vitaminac, one ounce three times a day), Max Kahn found a diminished indican output but an increase in the total ethereal sulphates of the urine, a result admitting of different explanations. In my experience most of the cases with intestinal putrefaction can be freed from this condition quite as quickly by the more palatable, more available and less expensive sweet milk, especially with the addition of lactose or starchy foods to make a lacto-farinaceous diet. As a matter of fact I am continuously seeing patients who have been on *acidophilus* milk in large daily quantities for months, or even a year or two, right up to the time of coming to me, and have even been having *acidophilus* germs injected into the bowel, yet who still show considerable intestinal putrefaction. A number of these patients have acquired sour stomachs from the lactic acid germs, some have developed irritated bladders from acid urine, and some have suffered from muscular rheumatic pains. Lactic acid milks are not constant, for their acidity increases from day to day so that eventually they become so sour as to be undrinkable.

In the use of acid milks I feel much like the consultant of that interesting book "A Corner in Harley Street" who wrote to his old aunt who had recently taken up the buttermilk fad, "Yes, buttermilk is a good food if you like it, personally I like mine sweet." Still if you cannot get patients to take the plebeian sweet milk, perhaps you

can induce them to take *acidophilus* milk because it seems like a medicine and is fashionable and expensive.

What I have said indicates to you that I do not consider lactic acid milks to have specific virtues because of the particular germ that is present, whether it be *Bacillus acidophilus* or *B. Bulgaricus*. Nevertheless, I do not look upon them as worthless. As a matter of fact in some cases any of these lactic acid milks may have real value. They may be good substitutes for flesh protein in those who eat too much flesh or ought not to eat meat at all, and who do not have acid stomachs or rheumatic tendencies. They have a curd that is fine and readily digestible, and sometimes they are well tolerated by stomachs that rebel at sweet milk. They are especially well taken by those with achlorhydric stomachs. They contain less fat and sugar than sweet milk, hence have a lower caloric value. There is some evidence that acid milks or even lactose alone will promote the absorption of calcium and phosphorus, but the matter is not finally settled.

In regard to *acidophilus* preparations other than milk, Bass (1922) reported a research in which among those examined he found absolutely worthless all commercial cultures and tablets that purported to contain living *Bacillus acidophilus*. In fact, of the best of the tablets examined "it would take one billion to contain as many bacilli as are contained in one liter of *acidophilus* milk." Recently, James published the results of a similar study on commercial liquid broth and milk cultures, jelly cultures, tablets and powders which purported to contain *B. acidophilus* or *B. Bulgaricus*. Of 107 samples examined only 13 yielded the species claimed on the label in reasonably pure form and in satisfactory number.

Eggs are good food for invalids, and like milk contain all the elements necessary for the growth of the animal body, but owing to their sulphur containing proteins they may be putrefactive. Raw eggs are non-irritant in the stomach, but as shown by the experiments of Osborne and Mendel at Yale, they are not fully digestible. After raw eggs these investigators were able regularly to recover egg albumin from the feces, while they were unable to do so if the eggs were cooked to the point of coagulation of the albumin. If raw egg albumin is not digested it is very putrefactive in the intestines. Still the glass of milk and egg may be a justifiable prescription if there is no intestinal putrefaction, for Hawk found that raw eggs mixed with milk prevent the formation of hard milk curds and promote the digestion of the milk, while it has also been found that this fine subdivision favored the digestion of the egg. Hard boiled eggs digest readily if in fine subdivision, otherwise not.

*Flesh Foods*—Beef, the beef of Old England,

has been a mainstay of the healthy and aggressive stock of the white races for centuries. Why then must all those who desire health nowadays be forbidden beef? How much we hear of red meat and white meat, dark meat and light meat! The red meats are charged with containing a greater amount of extractive, that is, substances which can be extracted by water, chiefly creatin, the nucleins, and the xanthine bases which favor the production of uric acid. Yet over twenty years ago, Oster and Rosenquist demonstrated that the purin content of light and dark meat was practically the same, and that there were greater differences in the percentages of nuclein and purin in the flesh of young and old animals of the same species, the flesh of different individuals of the same species of the same age, even pieces of meat taken from different parts of the body of the same animal, than were found on an average between those of chicken and beef. These findings were corroborated by J. Walker Hall of England. Von Noorden many years ago declared that "it is high time that the old prejudice against dark meat should be abandoned and the true facts of the case be recognized." Hutchinson, Gaultier, Strauss and other food experts since that time have agreed with these findings, yet daily I am confronted with the statement that "on my doctor's orders I have eaten no red meat for one or two or three years" as the case may be, and the patient may immediately add, "I have eaten so much chicken that I shiver when I see a hen." Virtuous obedience to futile command! The profession is responsible for this red meat fallacy, and if it was high time twenty years ago it is certainly high time now for medical men to abandon it. Beef, lamb, chicken, turkey, veal, pork, and the other flesh foods are equal producers of extractive, the only exception being the flesh of fish which produces only about half or two-thirds as much, and fat free beef, i. e., beef steak, which runs slightly higher than the average. When meat is boiled or stewed it has about the same equivalent as fish, for nuclein and hypoxanthin pass into the water. But Hawk says that as the extractives are strong gastric stimulants there is a distinct loss in gastric digestive power if the extractives are removed, and that meat deprived of extractives shows a greater amount in the stools, i. e., undigested, than unextracted meat.

Furthermore, from an extensive study of stools and the returns from colon irrigations, I long ago reached the conclusion that chicken is distinctly more putrefactive in the intestine than any other of the ordinary flesh foods, and these earlier observations have been confirmed by subsequent experience. It is my belief that chicken has hurt more people than has beef.

The only significant differences between

light and dark meat are the amount of blood present and the amount of connective tissue. In the breast meat of young chicken Mitchell, Zimmerman and Hamilton found only 4 per cent of the nitrogen in the form of connective tissue, while in the thigh muscles of the same animal the nitrogen of the connective tissue might reach 15 per cent. But this merely relates to the toughness and not to extractive, for while the meat of older animals contains more hypoxanthin, that of younger animals contains more nuclein. The difference is largely dispelled by cooking, which causes the white fibrous tissue to lose most of its toughness. For this reason I never use *raw meat*, even in the much used scraped beef sandwich. Cooking has no effect on the yellow elastic tissue which we largely discard as gristle.

*Bacon*, so often recommended for children and invalids is, like other preserved foods, rather resistant to the digestive juices. Its fat shows a low digestibility. On a diet of beef and bacon containing 96 grams of fat represented essentially by the bacon, Gaultier recovered 172 grams of fat in the feces, while with the same amount of fat supplied by milk he recovered only 3 grams. Hawk, Rehfuess and Bergheim have demonstrated that bacon takes  $1\frac{1}{2}$  times as long to leave the stomach in normal individuals as fresh pork, sausage or ham.

*Fruits*—From the intestinal point of view fruits furnish considerable indigestible roughage and other residues which tend to make them laxative, and they may also be laxative through the cathartic acids and salts which they contain. For example, orange, lemon and grape-fruit contain potassium citrate and also free citric acid which forms sodium citrate in the bowel. Thus the eater of the fruit obtains a dose of laxative citrate. Grapes contain potassium bitartrate or cream of tartar which becomes Rochelle Salts in the duodenum. The skins of fruits bear numerous bacteria and yeasts, and in some cases have been found to carry cysts of protozoa and eggs of worms. If the skin is not removable this may be important. Orange juice and orange are different foods, for after orange the stools invariably contain chunks of orange tissue and many orange cells full of unliberated orange juice. The same may be said of grape-fruit. Bananas and oranges are among the best furnishers of vitamins, but bananas should either be very ripe or be cooked.

Fruits are base or alkali-formers to the system and that is one of their virtues, but in the stomach they are distinctly acidifiers, tending to irritate and induce a hypersecretion of gastric juice. Therefore, in hyperacidity conditions they are to be avoided. Cooked fruits tend to be less irritant than raw fruits, for they are in a better condition of disintegration. In many conditions of the bowel, for example, mucous

colitis and spasticity fruits sometimes make fermenting acid fibrous masses which do far more harm than could be produced by any of our mild tonic laxatives. Indeed in many of these cases the stoppage of coarse fruits and vegetables permits the bowels to move more normally.

**Mushrooms**, reputed in some quarters to have a high food value, are for the most part indigestible and are readily recovered from the feces. In a putrefactive type of bowel they may be highly putrefactive.

**Bran** is a substance whose usefulness for man has been over-rated. Thirty-three per cent of it consists of pentosans which are not digestible by humans. According to Osborne and Mendel it is irritating to the stomach and intestines, it is therefore contraindicated in hyperacidity, mucous colitis and other states of gastrointestinal irritability.

**Bread**—Graham bread contains the whole wheat, while whole wheat bread contains only part of the husk of the wheat kernel, but because of the bran present and the oil of the embryo both are less digestible than white bread and may be irritant in both stomach and bowels. White flour is bolted and is therefore in very fine subdivision. Murrill, Mattill, Carman and Austin found only 87.2 per cent of the proteins of whole wheat flour digestible by humans, while of white flour they found 99.5 per cent of the proteins digestible, and the liberation of the starch of bread is dependent on the digestion of the gluten part of the protein. Whole wheat flour does not keep well, and though it furnishes vitamin B, and a slight increase of salts its bread is in general a less valuable food than the more digestible and more palatable white bread. In this connection McCollum and Simmonds remark that dyspeptics or others "would gain much more through adhering to a diet well-balanced than through adopting this or any other dietary whim or fad." Osborne and Mendel feel that the foods usually eaten in an ordinary diet supplement the deficiencies of white bread better than the wheat embryo itself. In any case the yeast used in preparing bread makes up any vitamin B deficiency.

**PEPSIN**—The Pharmacopoeia standard for pepsin is that in a weak hydrochloric acid medium it must be able to digest 3000 times its own weight of coagulated egg albumin (in 2½ hours). That is, one grain of pepsin can digest at least 6¼ ounces of the white of egg which is one-eighth protein. It can digest other animal proteins at about the same rate, so that in round numbers we can say that 5 grains of pepsin will digest the protein of one pound of roast beef, lamb, chicken or fish, or a dozen eggs.

Here is a drug of enormous potency, yet it is one that is absolutely without indication in

therapeutics so long as the gastric juice contains any pepsin at all. Its sole use is when there is complete absence of pepsin and if employed at all it should be accompanied by hydrochloric acid to make an artificial gastric juice.

The digestive ferments are powerful substances, and if they are present even in small amounts there is no occasion to prescribe them.

**INTESTINAL ANTISEPTICS**—Of the many substances administered by mouth for this purpose none has proven satisfactory. This may readily be understood when the large capacity of thirty feet of bowel suggests the degree of dilution of the antiseptic that must take place. Remedies used for the purpose are either absorbed, split up or hopelessly diluted before they arrive at the lower reaches of the bowel.

Dragstedt, Dragstedt and Nisbet at the Mayo Clinic showed the impossibility of sterilizing the intestines by any ordinary antiseptics. In tied off intestinal loops they placed 70 per cent alcohol, ether, 2 per cent lysol, 5 per cent, silver nitrate, a saturated solution of zinc chloride, 5 per cent phenol, 10 per cent thymol in alcohol, a saturated solution of salol, a saturated solution of quinine sulphate, Dakin's solution, a solution of mercuric bichloride, and the solids, camphor, menthol, naphthalin and betanaphthol. In all these cases they failed to obtain sterilization. How then could we expect an antiseptic effect from such a small dose as could be given by mouth? The new dyes, acriflavin and gentian violet may prove to be better through their specific affinity for certain of the bacteria, and in 1-4000 solution by rectum they are being used in ulcerative colitis with some apparent benefit.

**THE BOWELS**—Hurst says "I sometimes wonder whether (the colon) is not more sinned against than sinning, for what with attacks from above with purges, attacks from below with douches, and frontal attacks by the surgeon its sorrows are numerous and real."

**CONSTIPATION**—When a patient comes for constipation an examination of the rectum will determine whether the site of his constipation is in the rectum or higher up. Normally the rectum is empty and feces passing into it give the subjective sensation of a desire to empty the bowels. Therefore if the rectum contains a fair amount of feces yet the patient has no desire to go to stool, he has rectal constipation. Hurst says that over fifty per cent of all cases of constipation are of this type. It is usually due either to lack of tone and sensitiveness of the rectal wall, to injury to its supporting tissues as in rectocele, or to anal spasm as from painful hemorrhoids, fissure or fistula.

In rectal constipation it is needless to foist

a lot of laxative drugs and coarse foods upon the whole alimentary tract. When due to atony it can be overcome by daily efforts to have a stool at a regular time, preferably after breakfast, by paying attention to the slightest sensation of desire to defecate, by keeping the feces soft with mineral oil by mouth, and by local treatment. This may be a glycerine suppository or an enema of a cup of water on arising, or the instillation of 2 or 3 ounces of olive oil at bedtime to be retained over night. Such an amount of oil can be conveniently inserted by the patient with a soft rubber ear syringe. If the trouble is a rectocele surgery is indicated. If painful hemorrhoids are the fault the oil at night and a 5 grain anesthesin suppository in the morning will usually suffice.

But if the site of the constipation is higher up, then our problem may be a more difficult one. People do not come to the physician for a slight sluggishness of the bowels, so in a patient presenting himself for constipation it is well to obtain a good history of the extent of his previous treatment by laxatives and coarse foods so that we may aim better at our object. Having satisfied ourselves that there is nothing surgical to deal with and having arranged for an abdominal support if there is ptosis, we begin our treatment by education and laxatives. The stock advice of an educational kind is about as follows. Whether you feel like it or not, go to stool every morning about the same time. When the desire to defecate comes on do not postpone going to stool, for the desire may disappear and fail to return. Take plenty of exercise. Drink a lot of water. Eat a sufficiency of a good mixed diet which contains plenty of roughage. You all know these rules. They are the standbys of the profession. But *exercise does not make the bowels move*. Dr. Meylan, Athletic Director at Columbia, has told me that among the students taking active gymnasium work over thirty per cent are constipated. A number of my patients with chronic constipation have been professional or college athletes and gymnasium instructors who work hard all day long or planters who spend much of their time in the saddle. Others have been day laborers, diggers, longshoremen, compared with whose daily performance 36 holes of golf are a mere bagatelle. On the other hand many persons of completely sedentary life have no constipation. *Water does not make the bowels move* for while too little water may result in feces of a dried out concentrated type and thus favor the development of constipation, nevertheless the ingestion of a whole gallon of it does not result in a laxative action but serves merely to activate the kidneys.

Normal food in normal amounts is the cause of normal defecation in normal people, and

undereating of food, which occurs in rundown conditions, is habitual with some women and is ordered by some physicians, is prone to result in constipation. Therefore in those not eating heartily strive to ensure a good appetite, with appropriate bitters if necessary, and in regulating the diet figure not only on its content of adequate residues but also on its ability to satisfy the palate so that the patient will eat it. Indeed, it is probably improvement in appetite that constitutes the apparent benefit in some cases from exercise. As a rule so long as undereating continues cathartic measures will have to be continued.

Foods that leave notable residues are whole wheat or bran breads, bran, the non-starchy vegetables such as carrots, beets, turnips, cabbage, lettuce and spinach and the fruits, including the coarse indigestible figs and dates. Being newspaper educated the patient will probably already have tried out these foods, for only after he has found them to fail does he consult a doctor. But the residues are such because they are indigestible, and there are many cases in which these coarse indigestible particles induce irritation in a sensitive stomach or bowel or result in an abnormal production of gas. Because of this they not only fail to overcome constipation but in some instances increase it. With a sensitive stomach or an irritable bowel, bland foods with mild doses of laxative will do more good and less harm than the coarse indigestible and fermentable messes that are so frequently swallowed. When using the bland low-residue foods a substitute non-irritant residue preparation may be provided, such as agar or mineral oil. My favorites are plain mineral oil and the cascara-agar preparation known as regulin. In mild cases these alone suffice to relieve and if continued long enough may result in cure. Many chronic neurotic patients take abundant laxatives and enemas because of a fear that if they do not have several liquid or soft movements every day they are headed for destruction. In these I find that regulin in doses of one or two teaspoonfuls with or after the meals or morning and night is often all that is needed to produce the normal soft formed stool, the patient's cooperation at the outset being secured by assurance that a temporary lack of bowel movements will do no harm and is a necessary preliminary to successful treatment.

Preparations of agar and mineral oil together have recently become popular, but like all emulsions they are mostly water. The Council of Pharmacy and Chemistry of the A.M.A., reports their content of oil and agar as follows: *Petrolagar*, petrolatum 61 per cent, agar 0.3 per cent, *Squibb's Petrolatum with Agar*, petrolatum 45 per cent, agar 1.3 per cent, *Agarol compound*, petrolatum 27 per

colitis and spasticity fruits sometimes make fermenting acid fibrous masses which do far more harm than could be produced by any of our mild tonic laxatives. Indeed in many of these cases the stoppage of coarse fruits and vegetables permits the bowels to move more normally.

**Mushrooms**, reputed in some quarters to have a high food value, are for the most part indigestible and are readily recovered from the feces. In a putrefactive type of bowel they may be highly putrefactive.

**Bran** is a substance whose usefulness for man has been over-rated. Thirty-three per cent of it consists of pentosans which are not digestible by humans. According to Osborne and Mendel it is irritating to the stomach and intestines, it is therefore contraindicated in hyperacidity, mucous colitis and other states of gastrointestinal irritability.

**Bread**—Graham bread contains the whole wheat, while whole wheat bread contains only part of the husk of the wheat kernel, but because of the bran present and the oil of the embryo both are less digestible than white bread and may be irritant in both stomach and bowels. White flour is bolted and is therefore in very fine subdivision. Murrill, Mattill, Carman and Austin found only 87.2 per cent of the proteins of whole wheat flour digestible by humans, while of white flour they found 99.5 per cent of the proteins digestible, and the liberation of the starch of bread is dependent on the digestion of the gluten part of the protein. Whole wheat flour does not keep well, and though it furnishes vitamin B, and a slight increase of salts its bread is in general a less valuable food than the more digestible and more palatable white bread. In this connection McCollum and Simmonds remark that dyspeptics or others "would gain much more through adhering to a diet well-balanced than through adopting this or any other dietary whim or fad." Osborne and Mendel feel that the foods usually eaten in an ordinary diet supplement the deficiencies of white bread better than the wheat embryo itself. In any case the yeast used in preparing bread makes up any vitamin B deficiency.

**PEPSIN**—The Pharmacopoeia standard for pepsin is that in a weak hydrochloric acid medium it must be able to digest 3000 times its own weight of coagulated egg albumin (in 2½ hours). That is, one grain of pepsin can digest at least 6¼ ounces of the white of egg which is one-eighth protein. It can digest other animal proteins at about the same rate, so that in round numbers we can say that 5 grains of pepsin will digest the protein of one pound of roast beef, lamb, chicken or fish, or a dozen eggs.

Here is a drug of enormous potency, yet it is one that is absolutely without indication in

therapeutics so long as the gastric juice contains any pepsin at all. Its sole use is when there is complete absence of pepsin and if employed at all it should be accompanied by hydrochloric acid to make an artificial gastric juice.

The digestive ferments are powerful substances, and if they are present even in small amounts there is no occasion to prescribe them.

**INTESTINAL ANTISEPTICS**—Of the many substances administered by mouth for this purpose none has proven satisfactory. This may readily be understood when the large capacity of thirty feet of bowel suggests the degree of dilution of the antiseptic that must take place. Remedies used for the purpose are either absorbed, split up or hopelessly diluted before they arrive at the lower reaches of the bowel.

**THE BOWELS**—Hurst says "I sometimes wonder whether (the colon) is not more sinned against than sinning, for what with attacks from above with purges, attacks from below with douches, and frontal attacks by the surgeon its sorrows are numerous and real."

**CONSTIPATION**—When a patient comes for constipation an examination of the rectum will determine whether the site of his constipation is in the rectum or higher up. Normally the rectum is empty and feces passing into it give the subjective sensation of a desire to empty the bowels. Therefore if the rectum contains a fair amount of feces yet the patient has no desire to go to stool, he has rectal constipation. Hurst says that over fifty per cent of all cases of constipation are of this type. It is usually due either to lack of tone and sensitiveness of the rectal wall, to injury to its supporting tissues as in rectocele, or to anal spasm as from painful hemorrhoids, fissure or fistula.

In rectal constipation it is needless to foist

Probably the chief factor in driving the constipated to seek relief is intestinal putrefaction with the production of toxins from the food. These toxins may produce headache, mental depression, nervous breakdown and other serious results. The effect on the disposition was noted by Moliere who so long ago wrote, "A 'Yes' from a person with constipation is more disagreeable than a 'No' from one whose bowels move every day."

*Mucous Colitis*—This is a poorly understood malady in which the bowel forms abnormal mucus in large quantities. In the severer forms it is regularly accompanied by intestinal putrefactive toxemia and various nervous or psychic phenomena. At times it may produce abdominal pain or even intense colic, but the disease in severe form is often present without colic. It occurs with frequency in both males and females of all ages.

The diagnosis is not always obvious and rests, 1, on the patient's history of passing slimy stools or the characteristic strings, plaques or skins of mucus, 2, on the finding of such mucus in the stools, or 3, on the recovery of the mucus by a colon irrigation. Since mucous colitis is an accompaniment of many surgical conditions it is requisite to recognize the presence of a diseased gall bladder or appendix, cancer of the bowel, a retroverted uterus or a torn and lax perineum. In the presence of any of these conditions medical treatment is futile. In nervous patients the colitis is frequently unrecognized, and a diagnosis of neurasthenia or neurosis is made. But such a diagnosis renders the outlook hopeless, for it ends the physician's investigative interest in the case.

These patients seek help not for the colitis but for persistent constipation or occasionally diarrhea, abdominal pain or distress, lack of physical energy, a falling off in business efficiency, mental depression or complete nervous breakdown. Conspicuous in some are lack of self-confidence, suggestibility and various phobias such as the dread of visitors, of riding in a train or of being alone.

A noticeable character of the disease is tiredness or fatigability, mental or physical, and a severe attack may be brought on by aggravation of this state by worry, as over money matters, a sick child, some skeleton in the closet or an approaching visit of the husband's relatives. It is characteristic that the patient regularly makes mountains out of mole-hills. Even a nagging wife may be a factor and you may have to say to her, "Madam, what your husband needs is a rest, one of you must take a vacation."

First then, we must instruct the patient "Never overdo, never do anything too much," i.e., never do enough physically, mentally or

emotionally to bring on fatigue. We try to arrange occupation, recreation and rest in proper proportions without allowing the patients to coddle themselves, and do not permit extra responsibilities such as club or church committee work, teaching Sunday School, etc. We do not allow breakfast in bed, the morning air being such that this time of day is best spent up and for part of the time out of doors, but we insist on a complete rest period after the midday meal and early to bed. As soon as the bowels, diet and daily habits are under good regulation we try to arrange a vacation whether it is a business man, a mother with family cares or an old maid daughter who is nursing an aged and infirm father. If at the outset they are too sick to carry out this plan it is seldom possible to get them well in home surroundings, therefore, we place them in the hospital under the care of a nurse where they will be under our personal supervision, where we can talk with them, encourage them and watch them, and where we can keep the family away as much as seems wise. Here we give them cold spinal douches, cold packs, cold rubbings up and down the spine, massage, hot applications to the abdomen during the rest period and other forms of physical therapeutics, as well as care of the diet and bowels and plenty of rest. We do not care to have them at the hospital without a personal nurse, for disinterested companionship is an essential of the treatment. And we do not permit them to return home until they are well relaxed. If one's local hospital is not satisfactory for this class of patient one can send them to some well-conducted sanatorium where fads do not prevail.

Whether at home or at the hospital the bowels must be looked after. We study these bowels with great care from the constipation intestinal putrefactive toxemia and mucus points of view. While mucous colitis may be present in diarrhea cases, clinical mucous colitis is practically always accompanied by constipation. And it may be taken as an axiom that if constipation persists the patient will not get well. It may be treated by an intelligent application of the methods already spoken of.

*Intestinal putrefactive toxemia* is especially prevalent in severe mucous colitis, and without doubt is responsible in many instances for the neurotic manifestations and the condition of physical and mental fatigability. It is therefore to be taken seriously into consideration. For a period it may require the complete abolition from the diet of the highly putrefactive protein foods, such as flesh, eggs, peas and beans. The last contain sulphur. I am told that in Boston baked beans do not putrefy, in New York they sometimes do. Dried beans

cent, agar 0.6 per cent. Agarol contains in addition 15 per cent of glycerin and in each tablespoonful three grains of phenolphthalein. None of these preparations contains more than traces of agar and all contain from 35 to 55 per cent of water. They may be suitable preparations for use, but it is well to know just what we are using.

The two softening agents that I value are mineral oil and magnesia, preferably the milk of magnesia, but these agents have little if any actual stimulating effect upon the bowels. Therefore in the really refractory cases of constipation while the softening agents may have some use we must resort to more pronounced laxatives. In the use of these we have several rules.

*Rule 1 Have the medicine taken every day and at the same time of day.* Per n administration never cures constipation.

*Rule 2 - Do not employ drastics.* These drugs, jalap, podophyllum, scammony, colocynth, etc., can readily produce inflammation. In my laboratory days all that we had to do to demonstrate acute colitis and acute nephritis was to close off the rectum of a dog and administer a good dose of the compound extract of colocynth or the resin of jalap. I have seen death in a woman from the failure of the bowels to move in response to excessive doses of these drastics, the autopsy showing this same acute nephritis and colitis. Drastics are local irritants capable of producing inflammation, and chronic constipation is never cured by compound jalap powder or compound cathartic pills.

*Rule 3 Do not allow the feces to be liquid for any great length of time.* A liquid consistency of the feces is most favorable to fermentation and putrefaction, in fact the feces may be nothing but sewage. Chronic constipation cannot be successfully cured by replacing it with diarrhea.

*Rule 4 Do not allow the feces to continue highly offensive.* It means putrefaction with all its accompanying ills. The nose is all the laboratory apparatus required to detect this.

*Rule 5 Note the character of the stools.* From time to time have the patient bring a full stool in a pint glass fruit jar. Patients think more of a doctor who examines stools, and stools tell the doctor a lot about the patient. Moreover, they need cause no trouble to the doctor, for the eye and the nose will, in a moment's time, furnish more valuable information than the laboratory.

Of drugs for chronic constipation the tonic laxatives excel all others. They are cascara, senna, aloes or aloin, and rhubarb, and perhaps also phenolphthalein. Even if these

drugs lie in the bowel they do not cause inflammation and their active principles if absorbed are eliminated without harm to the kidneys. As a rule too, their dose does not need to be increased but may be gradually reduced. They may be given in a single dose at night, as an aloin, belladonna and strychnine pill, a cascara pill or the fluid extract of cascara. At one time I frequently prescribed nightly doses of compound licorice powder which is a senna preparation, but found that the sulphur of this preparation sometimes makes a sulphide odor and sulphide poisoning. Many people chew a few senna leaves at bedtime. Others chop up senna with dates, figs and prunes and take a teaspoonful or two, or boil prunes and senna with water and drink it by the cupful.

But for cure rather than relief a better method though a more troublesome one to the patient is to give these drugs in small doses throughout the day, with in addition perhaps a dose of mineral oil for softening purposes. Often enough we have had ten minims of cascara three times a day give better stools than a single dose of a dram or two at bedtime. With tonic laxatives so administered we have seen satisfactory continuance of the movements though we progressively reduced the dose of the drug till finally it was dispensed with altogether.

A rather strong and not unpalatable bowel tonic preparation is a mixture of equal parts of fluidextract of senna, aromatic fluidextract of cascara and aromatic syrup of rhubarb, one or two teaspoonfuls after each meal. Because of associated stomach acidity we have had better results in the long run from some such mixture as sodium bicarbonate 5II, fluidextract of cascara 5III add rhubarb and soda mixture to make 5IV. Dose 2 teaspoonfuls an hour before lunch and dinner and at bedtime, i.e., at the empty period of the stomach. But it takes a long time to overcome chronic constipation and as the remedies must be continued for months they should be simple, and the doses and the prescription modified from time to time. To overcome cramps or true spasticity, the best addition to our prescription is belladonna.

A daily movement of the bowels is considered the usual desideratum, the daily excretion of a normal person on a mixed diet being a sausage an inch or more in diameter and 9 to 12 inches long. At the time of passage it should not have a highly offensive odor. But it is not *always* necessary that the bowels should be moved daily. Horace Fletcher, famed for his excessive mastication of food, came to have only about one action of the bowels a week, yet was in better health than ever before. On the other hand some patients do best on two or three movements a day.

Probably the chief factor in driving the constipated to seek relief is intestinal putrefaction with the production of toxins from the food. These toxins may produce headache, mental depression, nervous breakdown and other serious results. The effect on the disposition was noted by Molere who so long ago wrote, "A 'Yes' from a person with constipation is more disagreeable than a 'No' from one whose bowels move every day."

*Mucous Colitis*—This is a poorly understood malady in which the bowel forms abnormal mucus in large quantities. In the severer forms it is regularly accompanied by intestinal putrefactive toxemia and various nervous or psychic phenomena. At times it may produce abdominal pain or even intense colic, but the disease in severe form is often present without colic. It occurs with frequency in both males and females of all ages.

The diagnosis is not always obvious and rests, 1, on the patient's history of passing slimy stools or the characteristic strings, plaques or skins of mucus, 2, on the finding of such mucus in the stools, or 3, on the recovery of the mucus by a colon irrigation. Since mucous colitis is an accompaniment of many surgical conditions it is requisite to recognize the presence of a diseased gall bladder or appendix, cancer of the bowel, a retroverted uterus or a torn and lax perineum. In the presence of any of these conditions medical treatment is futile. In nervous patients the colitis is frequently unrecognized, and a diagnosis of neurasthenia or neurosis is made. But such a diagnosis renders the outlook hopeless, for it ends the physician's investigative interest in the case.

These patients seek help not for the colitis but for persistent constipation or occasionally diarrhea, abdominal pain or distress, lack of physical energy, a falling off in business efficiency, mental depression or complete nervous breakdown. Conspicuous in some are lack of self-confidence, suggestibility and various phobias such as the dread of visitors, of riding in a train or of being alone.

A noticeable character of the disease is tiredness or fatigability, mental or physical, and a severe attack may be brought on by aggravation of this state by worry, as over money matters, a sick child, some skeleton in the closet or an approaching visit of the husband's relatives. It is characteristic that the patient regularly makes mountains out of mole-hills. Even a nagging wife may be a factor and you may have to say to her, "Madam, what your husband needs is a rest, one of you must take a vacation."

First, then, we must instruct the patient "Never overdo, never do anything too much" i.e., never do enough physically, mentally or

emotionally to bring on fatigue. We try to arrange occupation, recreation and rest in proper proportions without allowing the patients to coddle themselves, and do not permit extra responsibilities such as club or church committee work, teaching Sunday School, etc. We do not allow breakfast in bed, the morning air being such that this time of day is best spent up and for part of the time out of doors, but we insist on a complete rest period after the midday meal and early to bed. As soon as the bowels, diet and daily habits are under good regulation we try to arrange a vacation whether it is a business man, a mother with family cares or an old maid daughter who is nursing an aged and infirm father. If at the outset they are too sick to carry out this plan it is seldom possible to get them well in home surroundings, therefore, we place them in the hospital under the care of a nurse where they will be under our personal supervision, where we can talk with them, encourage them and watch them, and where we can keep the family away as much as seems wise. Here we give them cold spinal douches, cold packs, cold rubbings up and down the spine, massage, hot applications to the abdomen during the rest period and other forms of physical therapeutics, as well as care of the diet and bowels and plenty of rest. We do not care to have them at the hospital without a personal nurse, for disinterested companionship is an essential of the treatment. And we do not permit them to return home until they are well relaxed. If one's local hospital is not satisfactory for this class of patient one can send them to some well-conducted sanatorium where fads do not prevail.

Whether at home or at the hospital the bowels must be looked after. We study these bowels with great care from the constipation, intestinal putrefactive toxemia and mucus points of view. While mucous colitis may be present in diarrhea cases, clinical mucous colitis is practically always accompanied by constipation. And it may be taken as an axiom that if constipation persists the patient will not get well. It may be treated by an intelligent application of the methods already spoken of.

*Intestinal putrefactive toxemia* is especially prevalent in severe mucous colitis, and without doubt is responsible in many instances for the neurotic manifestations and the condition of physical and mental fatigability. It is therefore to be taken seriously into consideration. For a period it may require the complete abolition from the diet of the highly putrefactive protein foods, such as flesh, eggs, peas and beans. The last contain sulphur. I am told that in Boston baked beans do not putrefy, in New York they sometimes do. Dried beans

and peas are more putrefactive than green beans and peas. After the return to meat and eggs in the diet it is a good plan to have a lactofarinaceous day once a week, a day when the diet is confined to such foods as milk, cereal, bread and potato.

To dislodge the mucus, which adheres very tightly to the bowel wall we give an occasional dose of castor oil, calomel and salts, salts alone, a compound cathartic pill or compound licorice powder, and in addition use colon irrigations. Occasionally we switch to daily doses of salts or a saline water for a week or two. But as a rule salts treatment proves only temporary in its value and seldom leads to a cure. The stronger purges should not be permitted too frequently, for they are irritative and prone to be followed by a day or two of bowel exhaustion. These patients too readily acquire the purge habit.

Colon irrigations we give usually once or twice a week or occasionally, depending on the severity of the condition. Our method is to use several gallons of plain warm water by the two-tube process, using as inlet tube a catheter about 24 French and as outlet tube a rectal tube 30 French. We hang the bag low to give about 1½ feet of pressure and the water is run in very slowly. For the first gallon we place the patient on the left side and for the rest of the irrigation on the back. We like the bowels to move before the irrigation, and if they have not done so cleanse them with an enema and then wait a short time for the defecation reflexes to quiet down. We do not give irrigations to move the bowels but for the purpose of getting out something from higher up which is not brought out by defecation, and just as we lavage a stomach with water until it is clean, so do we try to lavage the colon until it is clean. True, one can fill the colon with two quarts of water, have it pass to the cecum in 2 or 3 minutes as shown by the X-rays, and have it re-expelled. But does this suffice? No, it does not. The putrefactive intestinal area is sufficiently often the lower part of the small intestine and it may be only after 5 or 6 gallons of colon washing with the patient quite relaxed that the ileocolic sphincter opens and lets down the rotten putrefying stuff that we are after. (That mucous colitis is not strictly a colon disease may be inferred from the fact that a patient of mine, whose colon was completely removed by Sir Arbuthnot Lane down to the lower part of the sigmoid flexure, has all the symptoms of mucous colitis even to the colic, and passes mucous strings as much as 18 inches in length.) Moreover, the mucus of mucous colitis may take a lot of soaking before it can be liberated from the mucous membrane to which it clings so tightly. Sometimes when our irrigation has been unsuccessful in obtaining the mucus, a brisk cathartic the same night has resulted in the passage of large quantities of mucus apparently softened

by the water of the irrigation, and sometimes by foul putrefactive stuff completely missed by the 6 or 8 gallons of water employed in the irrigation. Cleaning diseased bowels is not an easy task, and the recent work of Alvarez and Freedlander would show that sidetracking is a common trick of the intestines. To normal people they gave beads with the food and found that many days and even weeks elapsed before the last beads were passed in the stools. Some of the subjects apparently normal in every way took a week to pass as much as 70 per cent of the beads.

Colon irrigations are being overdone at the present time as they were in the time of Louis XIV. It is recorded that Louis himself in the course of his life received several thousand intestinal douches and made them fashionable in the whole court circle (Hurst). Their exploitation in the hands of the ignorant is a crying evil of the times.

*Nervous Diarrhea*—What a nuisance this is to its victim. If my lady goes out to dinner or has in guests her bowels must move. If the students first class is at 9 o'clock, just at nine must he defecate, and he is late for class even if he has made every endeavor to empty the bowel by repeated visits to the toilet between six and nine. I have several lawyers who on this account have given up court cases and I knew of one man who was forced to abandon a professorial appointment because his bowels always moved just as he started his lecture even though he had left the toilet not five minutes before. These patients may find that defecation is insistent just as they are setting out to visit the doctor. One of them had to leave the elevated train five times between her home and my office.

These are cases for reassurance, explanation of the real condition and efforts to ascertain the original emotional cause. There must also be rational treatment of any real bowel trouble such as habitual constipation and mucous colitis. But they need in addition something as an emergency bowel sedative and for this we employ codeine. At the outset we give it in half grain doses to convince the patient that the remedy is effective, but we soon reduce this amount and generally end by providing ⅓ gram tablets, to be taken on special occasions only, such as a Directors meeting, an examination, a dinner party, the opera or an automobile journey.

Give these patients a simple remedy and so long as they carry it with them, many of them will never need to take it. But let them forget to take their remedy along and as soon as reminded of the fact their bowels want to move. Accessibility to a toilet also makes for tranquillity of mind and bowels while the reverse is disastrous.

*Flatulence*—In *tympanites*, whether postoperative or in typhoid fever or pneumonia, the remedy we value most is pituitary by hypodermic, the dose being 1 c c of pituitrin, surgical, repeated if

necessary every hour or two. At the same time we use enemata of soapsuds with the addition of two teaspoonfuls of essence of peppermint to the quart, hot stupes to the abdomen, a rectal tube being left in situ, and a reduction of the food to the simplest forms, such as broths, barley water, lemon or orange albumin water, peptonized milk, Kumyss, buttermilk or hydrochloric milk. The last is made by adding dilute hydrochloric acid Mxxv to one pint of water and to this adding one quart of milk, the whole being brought just to the boil.

*Ordinary bowel flatulence* may be due to the influence of a diseased gall bladder or appendix, to constipation or to excessive use of laxative measures which carry the food down too rapidly for proper digestion. Of the possible gas-producing foods probably the worst are the fruits and those that are sweetened, and in some people milk. Buttermilk and acidophilus milk have proven successful remedies in some cases but in others they are great producers of gas. But in normal people these foods do not cause distress, therefore our attention must be given more to what is wrong in the abdominal viscera than to the character of the food ingested. Gas pressure at night is often due to gas in the colon, though the pressure may seem to be in the epigastrium, and then the only measure of relief is an enema at bedtime and a hot water bag or electric pad to the abdomen.

*Stomach flatulence* is a bothersome thing. It may be due to swallowed air or in the chronic atonic stomach to fermentation in the stomach, the pylorus being closed by spasm as in ulcer and gall bladder cases, or to high general pressure and stagnation in the abdomen as in tympanites and ascites. In the acute case the immediate need is a strong carminative. In some cases it requires stomach lavage, the application of heat or mustard over the stomach, a large dose of sodium bicarbonate and peppermint and a cathartic. When chronically present or frequently repeated gas is quite likely to be a sign of a diseased gall bladder or adhesions. A good flatulence dose is half a teaspoonful of sodium bicarbonate with a teaspoonful of a mixture of equal parts of compound tincture of lavender aromatic spirits of ammonia and spirits of chloroform. To overcome stomach or bowel atony strychnine is our best drug. To overcome air-swallowing explanation of the habit, and a derogatory comparison of the patient with horses that crib is usually all that is necessary.

*Hyperacidity*—Of those who come for gastric disturbances the great majority have what is commonly known as a hyperacidity condition. It is probably a combination of gastric irritability with hypersecretion, and is often accompanied by pyloric spasm with epigastric distention. It may be due to local irritation as from irritating food, alcoholic drinks or an ulcer, it may be a reflex

from a diseased gall bladder or some other inflamed viscus, or it may be a manifestation of nervous tension.

The *alcoholic drinks* and the *indiscretions in diet* present no difficult problem. The *surgical conditions* require operation.

*Ulcer*, though not always accompanied by hyperacidity, represents a state of irritability. Recently in a masterly presentation, Dr. Frank Smithies gave some interesting statistics which I might summarize as follows. Assuming that in the United States at present there are sixty million individuals at or past the adolescent age, 2,200,000 of them at present harbor or at some time will be affected with peptic ulcer. If all these are treated by surgery there will be an operative mortality of at least 7 per cent, i.e., 154,000 will die of the operation. Of those with only one operation there will remain a digestive morbidity in 30 per cent, or 579,000 persons. Following supposedly successful surgery, 46,000 will come to at least one secondary operation.

Were peptic ulcer treated wholly by surgery one could expect an annual operative mortality of 9,420, excluding deaths from hemorrhage. Were all ulcers treated by non-surgical procedures, the annual mortality would be 7,200. Therefore, as a cause of disability and death or as a field in preventive medicine peptic ulcer presents a problem commensurate with that of tuberculosis, cardiovascular disease, cancer or diabetes.

In considering how to handle a case of ulcer of the stomach or duodenum, the first requisite is a decision between medical and surgical treatment. In 1923 at a meeting in New York to discuss this question I was pitted against seven surgeons who for the most part differed from me, by contending that in practically all cases an ulcer called for surgery. Last year I was chosen to represent the medical side on two great occasions, at one of which Dr. Finney of Johns Hopkins, and at the other Dr. Leahy of Boston took the surgical side, and we proved to be in complete agreement. Dr. Finney said that he no longer operated for ulcer unless first a medical man, preferably a gastroenterologist, had pronounced the case a surgical one. Dr. Leahy said that in the past three years he had operated upon only 13 per cent of the ulcer cases that came to his clinic, for he had learned that in most cases competent medical treatment would leave the patient better off than surgery. Dr. Medill expressed the same sentiment several years ago. These opinions represent well the present trend of thought, and today both surgeons and physicians are in complete accord that some ulcers are best treated by medical means and other ulcers are best treated by surgical means. I might add that at the Mayo Clinic a considerable number of ulcer cases are now being treated by medical measures alone.

We are frequently told that operation should be the method of choice because of fear of hem-

orrhage, perforation or change to cancer in the future. But I have had more cases of hemorrhage in patients after operation than in patients undergoing medical treatment. I have never had a case of perforation in any patient while under medical treatment, though there are many cases on record of perforation not once but twice or three times in patients who had had an operation. Moreover, in many instances new ulcers have developed in duodenum and stomachs after operation, though the conditions established for the cure of ulcer had continued to be entirely satisfactory from the surgeons point of view. So surgery is not by any means a sure cure for ulcer, or a sure preventive of hemorrhage, perforation or recurrence.

As to the future development of cancer, the danger in a duodenal ulcer is practically nil, in gastric ulcer it is present in perhaps five per cent. But there is no evidence that a gastric ulcer cured by medical measures is more prone to develop cancer than an ulcer cured by surgical measures. In other words, if the ulcer is cured it is cured no matter what the means. Therefore the claim that surgery alone forestalls the development of cancer is not well founded.

Balfour stated that during a fifteen year period of operation at the Mayo Clinic cancer has been known to develop in 75 out of 1,280 cases operated upon for gastric ulcer. There were 195 deaths in all following satisfactory recovery from the operation, and he believes that many of the other 120 must also have died of cancer. These known cases developed after every type of operation and no less frequently after resection of a portion of the stomach than after gastroenterostomy with excision of the ulcer by the knife or cautery.

As there is a high mortality from ulcer operations, as the effects of unsuccessful surgery are sometimes irreparable and even disastrous, and as there is a more or less permanent digestive morbidity in 30 per cent of those operated upon I believe that we are not justified in employing surgery for the cure of ulcer for cases that promise to do well by medical treatment.

In other words, in deciding for or against surgery in ulcer cases I advise surgery only if I can honestly tell the patient that I believe that the probable dangers and disadvantages of surgery are distinctly less than the probable dangers and disadvantages of non-surgical treatment. This excludes operation in all ordinary cases of ulcer.

*Surgery*—I favor operation at the outset in the perforating or penetrating ulcers, in those with repeated copious hemorrhage, and in those with obstruction. In these types medical treatment is futile or dangerous and cannot be justified. In all other cases I favor medical treatment at the outset, but I do not hesitate to recommend surgery if in spite of good medical treatment there

is persistence of pain, nausea or sour stomach, there is recurrence with violence following a symptom-free period, or if I discover that the patient either because of difficult circumstances or difficult temperament cannot or will not faithfully carry out a prolonged medical scheme.

But it is not to be supposed that in recommending surgery I feel that then all will be satisfactory, otherwise I should recommend it in all cases. But surgery is merely an attempt to make the best of a bad job. Or, as Crile said, "to perform a gastro-enterostomy for an ulcer is a confession of failure, i.e., of failure to make a good stomach, just as much as amputation of a leg is a confession of failure to make a good leg."

*The Medical Treatment of Ulcer*—There are four degrees of management for ulcer, under each of which patients are known to get well. They are 1. No treatment at all, i.e., spontaneous cure, 2. The ambulatory medical treatment, 3. The bed medical treatment, and 4. The surgical treatment. I have seen a number of serious results from ambulatory treatment, so it is my practice to demand that my patients shall stay flat in bed for at least three weeks. It is my custom at the outset to use the milk, cream and egg method, beginning with peptonized milk the first few days to avoid the formation of curds. I have the patient in bed for several reasons: to give him mental and physical rest, to make the requirement of food less, to favor stomach emptying and to eliminate a gravity drag on the duodenum if it is adherent. I feed at frequent intervals, every hour if possible, in order to keep the patient's stomach in a state of contraction which favors healing, to give him enough food and to forestall hunger pains. I allow him to get up to the toilet. I do not allow any fruit whatever in the first three months except perhaps after 4 or 5 weeks a little orange juice once a day.

On the other hand, Dr. Smithies of Chicago, whose excellent gastrointestinal work is so well known, does not employ milk at first but rather thin water gruels made of rice, cream of wheat, oatmeal, sago, corn-meal, cauliflower, beans, peas and boiled onions. He also allows orange or grape-fruit as desired. At the end of two weeks he begins skimmed parboiled milk, and after three weeks he allows prune-whip, watermelon, cantaloupe, etc. He gives atropine or belladonna and no alkalies. I give no atropine or belladonna and alkalies in moderate quantities only. The Sippy cure calls for alkalies in enormous amounts. Sippy used routine nightly lavage. Smithies and I do not use routine lavage. Judging from their statistics we have about equally good results.

What then constitutes a medical cure for ulcer? Any method of treatment that will keep the patient nourished and abolish the irritability of the stomach, if such treatment is continued long enough. At the outset I will not attempt to give

the arguments for my method against theirs, or for theirs against mine, but would suggest that each practitioner adopt a definite basal method, so that by experience he will come to know when it should be modified, for modified to suit each patient it needs must be

Alkalies are much employed in ulcer cases and by many are believed to be healing, though Dragstedt did some work which suggests otherwise. He made artificial lesions in the stomachs of dogs and infected them with colon bacilli. This resulted in ulcers. In the stomachs with normal or high acidity the ulcers healed just as quickly as in the stomachs kept alkaline with frequently repeated doses of alkalies. In practice those who treat ulcer cases with small quantities of the alkalies get practically the same results as those who use alkalies in large quantities. In the latter case alkalosis has sometimes been a bad complication. But whether or not alkalies promote the healing of ulcers, they do help to give relief from the distressing symptoms which bring the patient in for treatment. Only they do not need to be given in enormous quantities or for many days.

In using alkalies it must be remembered that their action is not confined to the neutralization of acid. In fact, one cannot necessarily be substituted for another of the same antacid equivalent. Frequently a very small amount of alkali with a carminative will give as much relief as a much larger dose of alkali without the carminative, and not infrequently alkalies will give complete relief from stomach pains in conditions with gastric subacidity or even complete achylia gastrica. In spite of experimental proof that sodium bicarbonate has poor antacid value it seems to me to have given the best results. Perhaps this is because it liberates the carminative carbon dioxide gas.

In ulcer, aside from acute perforation the worst complication is *dangerous hemorrhage*. If the loss of blood is gross but not enough to produce obvious effects of hemorrhage on the patient it will usually suffice to put the patient in bed with head low, to give a hypodermic of morphine sulphate gr  $\frac{1}{4}$  to promote quiet, with strychnine sulphate gr  $\frac{1}{30}$  to give contractility to the stomach, and to administer 20 c.c. of thromboplastin solution or 2 c.c. of hemostatic serum subcutaneously to increase the coagulability of the blood to a point beyond the normal.

If the hemorrhage is accompanied by weakness, fainting, air-hunger and profound anemia these measures should be supplemented by transfusion and mechanical measures to overcome collapse. If the stomach is distended and the bleeding seems to persist lavage should be employed to empty the viscus. If the bleeding seems to have stopped lavage is contraindicated. If profuse hemorrhage, whether gastric or duodenal recurs two or three times in as many days I should

advocate transfusion followed by surgery, but it is the consensus of opinion that at the time of profuse gastric hemorrhage immediate surgery is contraindicated.

For an arbitrary period of three days following hemorrhage we allow no food or liquid by mouth, saline to allay thirst being given by rectum every 6 or 8 hours and a daily cleansing enema. The subsequent treatment is the usual medical treatment.

*Distention* is a common complication of ulcer and it usually means closed pylorus, a pylorospasm which shows that irritability is not overcome. It should be watched for by daily percussion of the stomach. It may be relieved by heat to the abdomen and an alkaline carminative such as sodium bicarbonate and peppermint. If persistent it calls for lavage, a cathartic and a return to the simplest diet with plenty of alkalies. If it is due to milk intolerance it demands a milk-free diet, at least for a few days. If not soon relieved it suggests the need of surgery.

In all cases the medical treatment of ulcer calls for prolonged care in the diet, and cure should not be accepted under many months. It is perhaps the failure of persistence in the treatment that is the most frequent cause of failure to cure.

*Nervous Tension*—But people with troubles, people that are tired and exhausted, people who face trying ordeals, people who are troubled with attacks of conscience, especially the young, may suffer as much from the empty pain three or four hours after meals and in the middle of the night as any ulcer case. Having by a proper study eliminated any local trouble, for many true ulcers are mistaken for nervous dyspepsia, your subsequent role is not so much medical as it is that of a broad-minded sympathetic human philosopher. Such patients may need nothing but recreation, diversion and reassurance. If a man likes fishing send him off to the woods, if the girl of the period feels that her mother nags her horribly arrange a visit to some friend where she will have some fun and freedom. While she is away reform the mother. Incidentally give a few rules for sensible diet, cut out the late hours, and prescribe a simple antacid medicine with such laxative action as may be necessary. "Medicine sometimes cures, it often relieves, it always consoles", it is never without a psychic effect as well as a physical one. If the nervousness is pronounced and the sleep unsatisfactory twenty grains of bromide after the morning and evening meals will work wonders. But primarily for these patients a clear understanding of their condition is essential.

The stomach responds keenly to mental states, and mental states are much dependent on the condition of the stomach and bowels. In testing the emptying time of the stomach for different foods, Rehfuess found that 100 grams of fried chicken taken by a student just before a worrisome chemistry examination required two

hours longer than usual to leave the stomach. In Cannon's roentgen ray observations with cats he found that if he annoyed a cat the motility of the stomach ceased. In our laboratory we had dogs with stomach fistulas to obtain gastric juice. If the attendant was cross with the dogs so that they would slink away and hang their tails between their legs we would obtain no gastric juice. On the contrary, if he patted a dog on the head and said "Hello, old fellow, how do you feel this morning?" the dog would wag his tail and we would get plenty of gastric juice. So I always say that to get good results you must see that your patients wag their tails. That is, while not neglecting the immediate cause of the sickness it is well to ascertain and to try and counteract the mental pang underlying. After all, one of the greatest accomplishments of the physician is to change unhappiness to happiness, inefficiency to efficiency, a bad disposition to a good one.

But most of our patients with hyperacidity symptoms do not have an ulcer, do not need sympathy and are unable to take a vacation, in which case they must be treated by simple measures while attending to their daily duties. For these a few sensible rules of living, drinking and eating must be supplemented by a prescribed diet and usually by alkaline and laxative medicines. We give them a diet that is bland, at the outset excluding such things as whole wheat bread, fruits, salads, coarse vegetables, coffee, tea and alcohol, but including the white cereals (hominy, rice and cream of wheat), white bread, toast and plain crackers, milk, cream, eggs poached or soft boiled, strained vegetable or cream soups, the plain meats, the starchy vegetables, potato, rice and macaroni, certain mashed and finely divided or strained boiled vegetables such as peas, beans, spinach, squash and carrots, and various milk and cereal desserts. If they are good milk drinkers we advise milk between meals. In addition we prescribe some such alkaline laxative mixture as

we have already alluded to, for example, sodium bicarbonate 3ii, fluid extract of cascara 3i, and rhubarb and soda mixture to make four ounces, dose, two teaspoonfuls, or we may prescribe a powder of sodium bicarbonate and magnesia with peppermint. We always have these taken about 1½ to 1 hour before lunch and dinner and at bedtime, that is, about the end of the digestive period. It may be an awkward time of the day for the patient to take medicine, but it is the time when the stomach needs it, and alkalies after meals are prone to stimulate the stomach to a compensatory excessive secretion. In addition I may give a dose of bromide for a few days after the morning and evening meals. As a rule bitters and nux vomica are contraindicated in all hyperacidity conditions.

Ladies and gentlemen, I have said enough. I have given you some of the ideas that aid me in my practice. Other men have other ideas which are just as good and we must resist the temptation to be dogmatic. But we are all working for the same end, helping our patients. The success of a physician is not rated by the amount of money he makes but by the esteem in which he is held. For the general practitioner this esteem is based largely on what he can do for his patients, that is, on his therapeutic success, whether this is brought about by pills, by surgery or by the helping hand. Many of our digestive patients are misfits, or victims of circumstances or of an overweening and misdirected ambition, yet what a lot we can do to increase their usefulness to themselves and others. They come to us with their digestive complaints because we are physicians, but with such our familiarity with the materia medica or our skill with a knife will avail them little unless also we are possessed of human understanding and sympathy. A knowledge of the family affairs is often of a great deal more value than all the results of the most elaborate laboratory tests.

## THE OFFICE TREATMENT OF GYNECOLOGIC PATIENTS\*

By WALTER T. DANNREUTHER, M.D., F.A.C.S., NEW YORK, N. Y.

THE gynecologic examination of a patient is a simple matter. The examination of a gynecologic patient is a complicated procedure, involving an adequate history, a complete physical inventory, and various laboratory tests, with a thorough investigation of the possible remote causes of pelvic symptoms. It is axiomatic that intelligent treatment is predicated on correct diagnosis. Now that our therapeutic resources have been so expanded that we are no longer limited to vaginal tampons, topical applications, curettage, and laparotomy, an accurate diagnosis is more than ever essential, in order that the remedial agents may be properly applied. It is quite evident that gynecological diagnosis and treatment are inevitably interwoven in any serious consideration of either phase of our clinical problems. Hence it is necessary to refer briefly to some of the important but oftentimes slighted details of the patient's examination.

The specialist soon comes to realize that woman's innate modesty obligates the physician to observe with meticulous care every refinement of his art when subjecting a patient to inspection of the genitalia. Yet, how often are these esthetic factors disregarded? A satisfactory examination of the abdomen cannot be made without the removal or displacement of all body clothing, but the patient will not be embarrassed if the breasts and lower extremities are covered with sheets. Again, when placing the patient in the lithotomy position, undue exposure can easily be avoided by holding a sheet at the waist level as she adjusts herself on the table. Tucking the center above the suprapubic region and draping each side neatly around the thigh and leg not only conceals all areas other than the vulva, but also keeps the sheet out of the examiner's way. It would be superfluous to say that sterile rubber gloves should always be worn when making a bimanual examination were it not for the fact that this is still far from a universal custom. The gloved hand is a silent recognition of the patient's sensibilities, as well as a protection to both patient and physician.

The first step in a pelvic examination is to pass a sterile catheter, lubricated with glycerine, and collect the urine in a sterile test tube. This provides a non-contaminated specimen for examination and insures an empty bladder, which is prerequisite for bimanual examination.

If a patient has leukorrhoea, it is advisable to take smears on glass slides. Fig. 1 repre-

sents the method I have adopted to identify the specimens easily. One smear should be taken from the urethra, one from the vagina, and one from the cervix. The smear from the urethra should precede catheterization, because the catheter is lubricated with glycerine, and the one from the vagina should be taken before

SMEAR FROM VAGINA

SMEAR FROM CERVIX

FIG. 1—Differentiation of unmarked smears

the introduction of the lubricated fingers or speculum. In the microscopic examination of smears adequate attention should be accorded the component elements of the secretion. The material secured from normal mucous surfaces always contains mucous threads, mucous corpuscles, pus cells, epithelia and microorganisms. An excessive discharge is a manifestation of either hypersecretion or infection. It is therefore evident that by observing carefully the proportionate incidence of the several morphologic features, and the identification of whatever pyogenic microorganisms are present, all smears may be properly classified.

Several years ago I reviewed the records of 600 consecutive private patients and discovered that 119, or about 20 per cent, had urinary symptoms. This makes it apparent that a knowledge of cystoscopy is indispensable to the gynecologist. Even though not equipped to carry out elaborate urologic procedures he can at least differentiate the simple cases,

\* Read before the Keuka Lake Medical and Surgical Association, Keuka Lake, N. Y., July 14-15, 1927.

hours longer than usual to leave the stomach. In Cannon's roentgen ray observations with cats he found that if he annoyed a cat the motility of the stomach ceased. In our laboratory we had dogs with stomach fistulas to obtain gastric juice. If the attendant was cross with the dogs so that they would sink away and hang their tails between their legs we would obtain no gastric juice. On the contrary, if he patted a dog on the head and said "Hello, old fellow, how do you feel this morning?" the dog would wag his tail and we would get plenty of gastric juice. So I always say that to get good results you must see that your patients wag their tails. That is, while not neglecting the immediate cause of the sickness it is well to ascertain and to try and counteract the mental pang underlying. After all, one of the greatest accomplishments of the physician is to change unhappiness to happiness, inefficiency to efficiency, a bad disposition to a good one.

But most of our patients with hyperacidity symptoms do not have an ulcer, do not need sympathy and are unable to take a vacation, in which case they must be treated by simple measures while attending to their daily duties. For these a few sensible rules of living, drinking and eating must be supplemented by a prescribed diet and usually by alkaline and laxative medicines. We give them a diet that is bland, at the outset excluding such things as whole wheat bread, fruits, salads, coarse vegetables, coffee, tea and alcohol, but including the white cereals (hominy, rice and cream of wheat), white bread, toast and plain crackers, milk, cream, eggs poached or soft boiled, strained vegetable or cream soups, the plain meats, the starchy vegetables, potato, rice and macaroni, certain mashed and finely divided or strained boiled vegetables such as peas, beans, spinach, squash and carrots, and various milk and cereal desserts. If they are good milk drinkers we advise milk between meals. In addition we prescribe some such alkaline laxative mixture as

we have already alluded to, for example, sodium bicarbonate  $\text{ʒiij}$ , fluid extract of cascara  $\text{ʒiij}$ , and rhubarb and soda mixture to make four ounces, dose, two teaspoonfuls, or we may prescribe a powder of sodium bicarbonate and magnesia with peppermint. We always have these taken about  $1\frac{1}{2}$  to 1 hour before lunch and dinner and at bedtime, that is, about the end of the digestive period. It may be an awkward time of the day for the patient to take medicine, but it is the time when the stomach needs it, and alkalies after meals are prone to stimulate the stomach to a compensatory excessive secretion. In addition I may give a dose of bromide for a few days after the morning and evening meals. As a rule bitters and nux vomica are contraindicated in all hyperacidity conditions.

Ladies and gentlemen, I have said enough. I have given you some of the ideas that aid me in my practice. Other men have other ideas which are just as good and we must resist the temptation to be dogmatic. But we are all working for the same end, helping our patients. The success of a physician is not rated by the amount of money he makes but by the esteem in which he is held. For the general practitioner this esteem is based largely on what he can do for his patients, that is, on his therapeutic success, whether this is brought about by pills, by surgery or by the helping hand. Many of our digestive patients are misfits, or victims of circumstances or of an overweening and misdirected ambition, yet what a lot we can do to increase their usefulness to themselves and others. They come to us with their digestive complaints because we are physicians, but with such our familiarity with the materia medica or our skill with a knife will avail them little unless also we are possessed of human understanding and sympathy. A knowledge of the family affairs is often of a great deal more value than all the results of the most elaborate laboratory tests.

tissue penetration are the most servicable. Both iodine and mercurochrome have this power to a limited extent. One of my assistants at the New York Post-Graduate Hospital, Dr Adolph Jacoby, suggested packing the cervical canal, after freeing it of secretion, with a small strip of gauze soaked in 2 per cent mercurochrome, and then filling the vagina with iodoform gauze (Fig 2). A few drops of mercurochrome solution are also injected directly into the structures of the portio with a dental hypodermic syringe. The gauze is left in situ for 48 hours and then removed and re-

FIG. 2.—The cervical canal is packed with a strip of gauze soaked in 2 per cent mercurochrome solution, and the vagina filled with iodoform gauze.

placed by the physician. I have followed this plan in many cases with gratifying results.

*Intracervical Galvanism* — The use of the galvanic current in the treatment of pelvic diseases was advocated by Apostoli as long ago as 1888. Unfortunately, this therapeutic innovation, like most new procedures, was misused, abused and misapplied, so that in the course of time it became of little more than historic interest. Yet, if one recalls that the negative pole of the galvanic current, applied

to a muscle covered with a mucous surface, promotes glandular secretion, relaxes muscle fibres, and stimulates circulatory activity, its possibilities in cases of cervical stenosis, ante-flexion, and uterine hypoplasia are apparent. The negative pole is connected to a copper cervical electrode with a long insulated shaft, and the positive pole to a felt covered flat electrode placed over the suprapubic region. Using 6 to 12 milliamperes of current and increasing the size of the electrodes from time to time, the cervix can be gradually and painlessly dilated. There is nothing that can be accomplished by forcible dilatation under anesthesia that cannot be done as well and with more permanent results in this way. I have used this method (often in conjunction with organotherapy) in cases of obstructive dysmenorrhoea and amenorrhoea due to hypoplasia for 20 years with the utmost satisfaction. Not infrequently pyogenic microorganisms can be found in the secretion after one of these applications when previously they could not be discovered.

*Cauterization of the Cervix* — Leukorrhoea is a symptom and not a disease. It is caused by constitutional disturbances, pathologic changes in the cervix uteri, and abnormal alterations elsewhere in the pelvic organs. In adults leukorrhoea is usually an expression of endocervical hypersecretion or infection. Until a few years ago, endocervicitis was a constant nuisance to the general practitioner, a serious problem for the gynecologist, and an excuse for much indiscriminate and useless curetting. Parenthetically, it is well to emphasize that Cullen and others have demonstrated beyond question that endometritis rarely exists and that leukorrhoea usually originates below the internal os. All cervical lesions should have immediate attention, because of the vicious circle whereby a simple pathologic condition may be converted into a serious one if neglected (Fig 3). In cases of acute cervicitis, all instrumentation and active treatment should be avoided. Local applications not only are of no avail, but they may even intensify the symptoms. Chronic endocervicitis, on the other hand, requires local treatment. It can be cured by (1) the electric cautery, (2) a Sturmdorff tracheloplasty, or (3) amputation of the cervix. For the majority of cases cauterization suffices. It can be used in the physician's office without anesthesia.

A small wire tip should be selected and applied superficially. One must not be too ambitious to do too much at one sitting, and the treatment should not be repeated in less than ten days. Before the cauterization, excessive mucous must be wiped away. The cautery will operate better in a dry field, because the small

amenable to local treatment of the urethra and bladder, from those requiring further investigation and the attention of a urologist. The distinction is important, as no urinary symptom or symptom-complex is pathognomonic of anything. The diagnosis rests much more on the objective than the subjective evidence.

*Vaginal Applications* — The most useful type of speculum for examining the vaginal walls and making topical applications thereto is the Ferguson, a plain cylindrical tube. After it has been inserted to its full extent, the vaginal walls are nicely exposed as it is slowly withdrawn. A medicated fluid may be poured in, and the medicament will follow the inner end as the instrument comes out, thereby bathing the mucous surfaces. In cases of senile vaginitis, pyroligneous acid used in this manner will quickly relieve the irritation.

The Ferguson speculum is well adapted to carrying out the Gellhorn treatment of advanced or recurrent cervical carcinoma. This consists of lubricating the speculum with a heavy coat of vaseline, placing the patient in the Trendelenburg position, gently curetting easily detached tissue masses, and pouring one ounce of acetone into the speculum, being careful that the acetone does not come in contact with the vaginal mucosa. After 20 minutes contact, the acetone is removed with pledgets of absorbent cotton and the vagina packed with iodoform gauze. Many of these patients can be kept quite free from bleeding and malodorous discharge by repeating this method of treatment occasionally.

Dusting powders are often useful in the vagina when it seems desirable to keep the surface dry. Equal parts of charcoal and iodoform are especially servicable as a deodorant. A mixture of acetanilid, one part, and boric acid, three parts, is convenient for general purposes.

*Vaginal Douches* — While douches are not given in the physician's office, they are probably more often prescribed in the treatment of gynecologic patients than any other remedial agent, and must be referred to briefly. A douche is indicated for the following purposes: as a cleansing agent, to promote hyperemia, as a deodorizer, as an antiseptic, as a contraceptive, and as a medicament. Routine douches are harmful and should not be used except for a specific reason. The patient should be instructed to detach the douche nozzle after using and keep it in a 2 per cent lysol solution. The following table enumerates the most popular therapeutic agents for vaginal douches, the strength in which each is ordi-

narily used, and the purpose which, in my opinion, each best fulfills.

Medicament	Amount in 2 quarts of water	Function
Sodium chloride	4 drams	promotes hyperemia
Boric acid	2 drams	cleansing agent
Bicarbonate of soda	3 drams	dissolves secretion
Lysol	1 dram	contraceptive
Potassium permanganate	5 grains	deodorant
Pyroligneous acid	3 drams	local sedative
Acridiflavine	30 grains	antiseptic
Mercurchrome—220	30 grains	antiseptic
Tincture of iodine	1 dram	gonococcicide
Mercury oxycyanide	5 grains	antituberc
Zinc sulphate	1 dram	astringent
Tannic acid	1 dram	astringent
Alum	1 dram	astringent

*Vaginal Tampons and Packing* — Cotton or wool tampons, impregnated with either plain or medicated glycerine, have been used since time immemorial and still enjoy wide popularity, despite their obvious inefficiency. Although a medicament is sometimes selected for its counterirritant properties, the chief purpose of most tampon applications is to promote pelvic depletion. This can be far more satisfactorily accomplished by means of strip gauze, because of its greater capillarity. If an ounce of glycerine is poured into the vaginal vault through a speculum and the vagina packed with a strip of 2 inch gauze bandage, subsequent drainage is so free that the patient will have to wear a vulvar pad.

*Topical Applications to the Cervix* — The portio of the cervix is covered with squamous epithelia, the cervical canal is lined with columnar cells. The former take the stain of iodine, the latter do not. Hence, when an eroded or ulcerated area is visible on the cervix, it should be painted with tincture of iodine. If it takes the stain, stimulating chemicals will effect a cure, if it does not, such applications are futile, and the surface must be cauterized. If an ulcerated area bleeds easily, it may be touched with a 10 per cent solution of copper sulphate. Malignant tissue will continue to bleed notwithstanding the application, whereas prompt cessation of bleeding suggests that it is probably not malignant. However, a biopsy specimen should be taken for microscopic examination and diagnosis in all such cases.

The chief virtue of the time-honored silver nitrate solutions lies in their stimulation of squamous epithelial regeneration, and their clinical application should be restricted to those cervical lesions which take the iodine stain. The inefficiency of silver nitrate in cases of infection is due to two factors: the incidental coagulation of albuminous material, and the inaccessibility of the microorganisms, which lie deeply in the racemose glandular crypts of the cervical canal. So if chemical agents are relied upon for the eradication of infection, those endowed with the property of

**Pessaries** — Stem pessaries are designed to maintain cervical dilatation. In occasional cases of acute anteversion with obstructive dysmenorrhoea, in which repeated office treatments seem undesirable because of the patient's youth and virginity, forcible dilatation and the

extensive cystocele, preliminary estimation of the size of the vagina

The uterus must not only be mobile, but must be restored to its normal position by the physician. The purpose of a pessary is not to correct a retrodisplacement, but only to maintain normal uterine poise after it has been replaced. If there is a pronounced prolapse or a large cystocele, the forcible downward pressure of the vaginal walls may be sufficient to push the pessary out through the vaginal orifice.

There are four types of hard rubber pessaries used in the treatment of mobile retroversion and retroflexion. The most practical for the largest number of cases is the one designed by Albert Smith. The only difference between the Hodge and Smith pessaries is that the Hodge has a wider anterior bar, so that it is better adapted to cases with a somewhat extensive perineal laceration. The Thomas pessary

FIG 6—Multiple Nabothian cysts

insertion of a stem are of some therapeutic value. But in general, it is bad practice to irritate the cervical canal by the prolonged contact of a foreign body, especially when the same result can be achieved otherwise without trauma. The cervix can be more easily and gradually dilated with the galvanic current.

The Gehrung pessary for cystocele, the cup pessary for prolapse, and other special contrivances are suited to exceptional cases only and need not be considered here.

Pessaries adapted to the treatment of retrodisplacements of the uterus are of great value in many cases and deserve more extensive discussion. It must be admitted that they promise no hope of permanent cure unless the displacement is discovered within six months of its occurrence. It is therefore advisable to insist that all patients return for examination six weeks after parturition or abortion. That is the ideal time to make the diagnosis, because if the uterus is replaced and maintained in position by a pessary, involution is promoted and a cure may be effected. In cases of long standing, the patient gets relief only so long as the pessary is worn. Incidentally, it also serves the purpose of demonstrating that maintenance of the normal uterine position will relieve the patient's symptoms.

**Pre-Requisites for the Application of a Pessary**—Bladder empty, uterus replaceable, uterus replaced, no extensive uterine prolapse, no

FIG. 7—Cauterization of Nabothian cysts

sary is a Smith pessary modified by a thicker posterior bar, to take up the slack when the posterior fornix is unusually capacious. Ring pessaries are servicable in the presence of moderate cystocele or beginning prolapse.

Before selecting a pessary for an individual case, the configuration, width and length of the vagina should be estimated. The proper

tip loses its heat when in contact with moisture. In cases of ectropion, three or four strokes are made on both the anterior and posterior lips in alignment with the cervical

FIG 3—The vicious circle of cervical lesions

canal (Fig 4). In most instances it will be necessary to repeat the application a few times and healing will not be complete until several weeks have passed (Fig 5). When large numbers of Nabothian cysts are present (Fig 6) they may be punctured and sterilized simultaneously by plunging the cautery tip directly into them (Fig 7). The glands lining the cervical canal can be destroyed by cautious applications within the canal. When an endocervicitis is so extensive that the entire portion is involved, the cautery strokes should

FIG 4—Cauterization of endocervicitis with ectropion

radiate from the external os (Fig 8). All cases that resist cauterization or that are complicated by extensive ulceration should be treated surgically.

**Diathermy** — The therapeutic value of diathermy, more correctly called bipolar endo-

thermy, in gynecologic diseases has been the subject of much recent controversy. Diathermy is usually considered as either surgical or medical, surgical when tissue destruction is the objective, and medical when relatively low degrees of heat are projected and concentrated in a diseased area. One of my staff members, Dr Mortimer N Hyams, has made painstaking clinical studies of a large number of patients and has arrived at the following conclusions: Surgical diathermy is an ideal method of treat-

FIG 5—Cervix healed after cauterization

ment for vulvar condylomata, urethral caruncles, infections of Skene's glands, and cervical polypi, the results from medical diathermy have been extremely gratifying in cases of acute uncomplicated urethritis, chronic adnexitis and inflammatory involvements of the utero-sacral ligaments, it will relieve about 50 per cent of cases of obstructive dysmenorrhoea. With the available armamentarium it cannot destroy pyogenic microorganisms in the deep crypts of the cervical glands, cure gonorrhoeal endocervicitis, and restore the cervix to normal.

**Intrauterine Irrigations** — Although intrauterine irrigations were popular twenty-five years ago, this method of treatment is now practically obsolete. Yet, in cases of spontaneous uninfected abortion that continue to bleed moderately, a few irrigations of the uterine cavity with an iodine solution (1 dram of the tincture to one quart of water) will often empty the uterus completely without curettage, particularly if the patient is given a daily intramuscular injection of pituitrin. These irrigations should never be given early in the treatment of abortion or in the presence of infection.

Having excluded parametric, perimetritic, and adnexal inflammation, catheterized the bladder, replaced the uterus bimanually, and selected the proper pessary, the patient's knees and labia should be widely separated. The pessary is then introduced obliquely, the fingers making firm pressure posteriorly as the instrument passes the introitus. The pessary is then rotated to the transverse position and

### THE CONSTRUCTION OF THE SMITH PESSARY

The cervix can move up and down through a small arc but cannot come any nearer the vaginal orifice

The upward bend of the posterior portion pushes the fornix upward and backward, and puts the utero-sacral ligaments on the stretch

The long upward curve of the anterior end of the pessary permits it to lie up out of the way in the narrow part of the pubic arch and allows for the upward pressure of the perineum and front part of the pelvic floor

The pessary is wider posteriorly because the fornix is capacious. It is narrower anteriorly so that it can lie up well in the angle of the pubic arch. The little transverse notch at the anterior end is to prevent pressure on the overlying urethra

FIG. 9—Construction of the Smith pessary, the cervix can move up and down through a small arc, but cannot come any nearer the vaginal orifice.

slid along the palmar surface of the fingers. As the posterior bar approaches the cervix, the fingers are turned (180°) lifted above the posterior bar, and push the bar under the cervix. The anterior end will then have disappeared behind the pubic arch. Now the fundus cannot retrovert, because there is no fulcrum on which the uterus can turn. It is advisable to insert the pessary without forewarning the patient.

**Incision and Drainage of Abscesses**—Three types of circumscribed suppurative accumula-

tions frequently present themselves: pelvic abscess, suburethral abscess, and abscesses of Bartholin's gland. They are mentioned chiefly to emphasize the fact that they are all best attacked with the patient under anesthesia.

A pelvic abscess is opened by drawing down the cervix, pushing a pair of sharp pointed scissors into the abscess cavity close to the uterus, and spreading the blades of the scissors widely.

A suburethral abscess found in the anterior vaginal wall should be excised rather than incised. Otherwise a fistula may result.

It is always a temptation to incise an abscess of Bartholin's gland over the point of greatest softening, which is usually on the vaginal side of the tumor. But if this is done, the dislocated duct may be severed and either a sinus or recurrence will follow. Complete extirpation is much better treatment than incision and drainage, but should never be attempted except under general anesthesia. The dissection invariably opens veins in the vaginal plexus, and several vessels deep in the wound must be tied. If, however, incision and drainage are selected, the incision should be placed well out on the cutaneous surface of the tumor.

FIG. 10—Method of introducing solutions into the urethra and bladder without instrumentation

**Urethral Applications**—While medicaments may be applied to the urethra by syringe injections, topical applications through a Kelly endoscope are more satisfactory. I have found a solution of 5 grains of iodine crystals in mineral oil useful. The only medium insures a longer contact than is the case when watery solutions are used. If one desires to apply a solution to the urethra or bladder without instrumentation, a blunt metal tip fitted to a record syringe serves the purpose well (Fig. 10).

**Intravesical Instillations**—These are used in all varieties of cystitis. The following table indicates the solutions which have proved most useful for the several types of inflammation in my own experience.

length is determined by inserting the fingers into the vagina, just as though measuring the diagonal conjugate diameter of the pelvis. The middle finger is pushed well up into the posterior fornix, and the distance to the pubic arch marked by placing a little piece of tape on the finger under the arch. The approximate width is estimated by separating the fingers in the vagina before their withdrawal. By palpating the pubic arch and the capacity of the posterior fornix, after a little experience it is easy to select a pessary of the size and shape that the patient needs. A properly fit-

FIG 8—Cauterization of extensive involvement of the portio

ting pessary should not be felt by the patient or cause her any annoyance, nor interfere with douching or coitus. The patient should be directed to return for examination after three days, to make sure that the pessary fits well. Thereafter it should be removed, cleansed, and replaced every six weeks. It is always better to risk using too small rather than too large a pessary. The worst that can happen to an undersized pessary is that it will slip out of

position or out of the vagina. On the other hand, one that is too large exerts undue pressure and causes local soreness. This is not only discouraging to the patient, but precludes further use of a similar appliance until all the soreness has disappeared. Naturally, if a pessary is inserted in the presence of parametrial or adnexal inflammation, the pressure of the foreign body will cause pain. So if complications exist, they must be treated and disposed of before the pessary is used.

Having replaced the uterus in its normal position, the only thing necessary to keep it there is some mechanical contrivance to hold the cervix back. The fundus is bound to stay forward, because it cannot slip backward without the cervix coming forward. The support might be a straight stick or anything else that would hold the cervix in its proper position (Fig 9). By keeping the two fixed points, the pubic arch and the posterior vaginal fornix, separated by a rigid bar, the cervix can move up and down through a small arc, but cannot come any nearer the vaginal orifice. If a straight stick were used, however, it would push sharply into the posterior fornix and make the patient very uncomfortable, so the end of the stick is bent upward to conform with the outline of the fornix and put the utero-sacral ligaments on the stretch (Fig 10). Having thus provided for the curve of the posterior fornix, it becomes necessary to make another curve in the anterior end, to allow for the upward pressure of the perineal structures (Fig 11). This long upward curve permits the pessary to lie up out of the way in the narrow part of the pubic arch. Since the vagina is a wide canal, a single thin stick would not keep the walls on the stretch, so it becomes necessary to place another stick parallel with the first and connect the two anteriorly and posteriorly (Fig 12). The posterior bar is wider because the fornix is roomy, the anterior bar narrower, so that it can lie well up behind the pubic arch. The little transverse notch and downward dip at the anterior end is to prevent undue pressure on the overlying urethra.

I have stressed the details of the principles upon which a pessary is designed because I have often seen pessaries misapplied and misfitted. Personal observations justify me in assuming that there are some men applying pessaries who do not thoroughly understand what these instruments are supposed to do, why they are constructed as they are, and how they should be adapted to the patient. Every curve in the outline of a pessary is put there for a definite reason, and if the reasons are appreciated, there will be no difficulty in fitting a particular patient.

Both had measles, mumps and whooping cough in childhood V R had appendicitis at the age of 26

7 W O and Wm O Male Aged 37  
General health of both always good Both had measles, mumps, whooping cough and chicken pox in childhood

8 R B and L B Male Aged 30  
General health of both always good Both have had whooping cough, measles and mumps

9 Mrs S and Mrs R Aged 27  
Both had measles, whooping cough and chicken pox Both have had diabetes mellitus for several years

A study of the fingerprints of Mrs S and Mrs R was made by C C Carmody, the Bertillon expert of the Detroit Police Dept The general patterns were found to be the same but there were definite differences in detail

In all of these cases the twins were strikingly alike in temperament and general ability

It may be of interest to note in passing that in the nine families represented in this series there have been seventeen sets of twins in the last three generations, a figure much higher than the normal expectation

There are many references in the literature to cases of twins having the same diseases or physical characteristics Francis Galton found that in some of the thirty-five cases he studied that not a single point of difference could be noted Several pairs showed the same peculiarities in their fingers Very frequently both became ill at the same time with the same diseases, not necessarily of a contagious nature

Ahlfeld<sup>1</sup> collected seven cases of similar malformations in duplicate twins

Miller,<sup>2</sup> in a study of thirty cases of duplicate twins found that there were twenty-three cases of similar or analogous malformations

A case is reported of diphtheria in female twins,<sup>3</sup> nine years old, in both of whom serum sickness and ocular paralysis appeared simultaneously The authors conclude that the coincidence of infection in certain twins proves identical reactions to infection

Galton mentions twins who were clerks by occupation, both of whom died of Bright's Disease one seven months after the other

Williams<sup>4</sup> says that he has seen Hodgkin's Disease in twin boys four years old and refers to the Lawford-Collins-Silcock case of melanotic sarcoma of the choroid in the left eyes of twin sisters Several cases of Mongolian idiocy<sup>5</sup> in both of twins have been described K Hale<sup>6</sup> describes a case of congenital dislocation of the hips in identical twins G H Parker<sup>7</sup> mentions a case of dementia precox in both of identical twins Freidreich's ataxia in twin boys was observed by J H Hess<sup>8</sup> A D Davis has described tripartite cleft palate and

double hare-lip in identical twins<sup>9</sup> Twins, both of whom had ichthyosis, Graefe's symptom, acromegaly and disturbances of growth are mentioned by Moller<sup>10</sup> Oudendal cites a case of cysts of the lung in twin sisters<sup>11</sup>

Carcinoma occurs but rarely in identical twins Warthin, Wolbach, Wells, F C Wood, Karsner and Greenough have never seen a case Warthin says that only three such cases have ever been reported in the literature and Bauer makes the same statement It is significant that in every recorded case in which carcinoma has occurred in one identical twin it has occurred in the other twin as well, and furthermore, the carcinoma has been of the same type and has involved the same part of the body in the one twin as in the other H Burkard<sup>12</sup> reports that twin sisters, twenty-one years old, developed each a fibroadenoma in the left breast at almost the same time and in the same quadrant The structure of the tumors was the same and both were removed at the same time H G Wells states that he knows of a case of twin brothers, both of whom have malignant tumors of the testicle<sup>13</sup>

These cases seem to give quite definite evidence that there is frequently inherited a general susceptibility to disease making the individual having such an inherited susceptibility much more likely to develop, under a favoring environment, the disease in question than is the average individual without such an hereditary susceptibility Further, not only can a general susceptibility to a given disease be inherited but it appears that there is also an inheritable specific organic susceptibility Thus, if cancer be the disease in question, then parents can transmit to their offspring not only a tendency to develop cancer under favoring conditions, but the probability that, if cancer does occur in the offspring, it will affect the same part of the body that it involved in the forebears

This discussion has purposely been made very brief It is the author's intention to develop the subject more fully at a later date

Inflammation	Silver nitrate, 1-10,000 to 1-5 000, carbolic acid, 0.5% to 2.0%	Syphilis	Oxycyanide of mercury, 1-10,000 to 1-5,000
Hemorrhage	Adrenalin chloride, 1-10,000, alum, 0.5% to 2.0%	Elaborate exposition of the topic I have represented would almost involve the condensation of a text book. Hence, it has been impossible for me to accord the several therapeutic measures mentioned the attention they deserve. The necessity for abbreviation has also precluded any reference to internal medication, hydrotherapy, organotherapy, radiotherapy, local anesthesia, etc., all of which are important therapeutic measures.	
Ulceration	Potassium permanganate, 1-7,500 to 1-3,500		
Tuberculosis	Oil of cajuput in olive oil, 20%, carbolic acid, 0.5% to 2.0%		
Gonorrhea	Tincture of iodine 3i to 1 quart, mercurochrome-220, 1% to 2%		

## IDENTICAL TWINS AND THE PROBLEM OF HEREDITY

BY FRANCIS PATTON TWINEM, M.D., NEW YORK, N. Y.

IN recent years there has been much discussion of the inheritability of various diseases. The number of diseases classed as hereditary has been diminishing until at present only a few, such as hemophilia and color blindness, are so classed. To be hereditary in a true genetical sense a disease must be determined by the actual chromosomal content of germ cells. In man, many of the small group of inheritable diseases are "sex-linked." The two diseases mentioned above, for example, belong in this class.

There are many diseases which appear to be hereditary but which are not so in actual fact. That these diseases appear to be inherited may be due to 1, intra-uterine infection, 2, close contact with parents in infancy and childhood, 3, inheritance of a constitution which makes the individual particularly susceptible to the development of certain diseases. It is number 3 which interests us most at present.

Our interest in this matter was aroused about a year ago by the study of a patient, Mrs. S., in the Harper Hospital, Detroit. Mrs. S. was an identical twin, and both she and her sister, Mrs. R., had had diabetes mellitus for several years. The idea occurred at that time that the study of medical histories of a number of pairs of identical twins would be of value in that it would throw some light upon the nature of the inheritance of disease.

According to the best authorities identical twins are of monozygotic origin, meaning that both were derived from one ovum. Consequently they begin life with the same endowment from the standpoint of heredity. As H. H. Newman has said, the matter of somatic segregation must be borne in mind, that is, whether, in regard to any particular factor, the earliest cleavages were differential or equational. (H. H. Newman, *The Biology of Twins*, U. of Chicago Press.) The members of a pair of identical twins should inherit the same general susceptibility to disease and, if there be such a thing, the same organic susceptibility to disease. Paren-

thetically, it may be stated here that about one-half of same-sexed human twins or one quarter of all human twins are monozygotic. Now there is no absolute method of determining whether a given pair of human twins is monozygotic, but we may consider that, if the members of a pair of twins have passed the age of adolescence and have always been so nearly alike physically and mentally that they could be distinguished only with difficulty, we are dealing with twins of monozygotic origin, i.e., the twins are duplicate or identical.

A study was then made of nine pairs of identical twins with particular reference to their medical histories. The main facts in regard to each pair of twins follow:

- 1 J. S. and E. S. Female. Aged 66. General health of both always good. Both have had diphtheria and marked hypertension.
- 2 W. L. and J. L. Male. Age of W. L., 49. J. L. died of lobar pneumonia at the age of 47. W. L. had lobar pneumonia at the age of 42. Otherwise the general health of both was good.
- 3 H. A. and A. A. Female. Age of H. A., 17. A. A. died at the age of 16 years. At autopsy a large ovarian cyst of unknown pathology was found. H. A. had an ovarian cyst of about the same size on the same side.
- 4 S. B. and Z. B. Female. Aged 42. General health of both always good. Both had scarlet fever and chicken pox in childhood. Z. B. had appendicitis at the age of 18.
- 5 R. S. B. and R. B. B. Male. Aged 28. General health of both always good. Both had measles, mumps, whooping cough and chicken pox in childhood. Both of these young men are excellent runners, each one having a record of approximately 9.26 for the two-mile run.
- 6 V. R. and E. R. Female. Aged 38.

have tried in the past and are trying at present, by means of mercurial inunctions given in the interval between the arsenical, to follow out the recommendation of the Public Health Service as to continuous treatment, but I have never been able to convince myself that our instructions are faithfully carried out.

Our treatment has changed somewhat as years have passed. Beginning in 1921 with a series of six injections of arsphenamin and six of mercury, each once a week, we have increased the number of injections as follows. We now give arsphenamin or neo-arsphenamin twice a week and salicylate of mercury once a week for six weeks, this constitutes a complete arsenical course, and in early cases is repeated twice, when possible, regardless of the reaction of the blood. The interval between courses is six weeks, thus giving the patients a chance to take a voyage and earn enough money to keep them through the next course.

The dosage is the same for both the arsenicals, namely, after the initial dose of 0.25 grams, 0.40 grams are given on Monday and 0.30 grams on Friday. On Wednesday, the patients each receive one grain of salicylate of mercury. This is the method attempted in all cases of less duration than a year. In the later stages, we are guided by the results obtained and the reactions of the blood.

During the period covered by this report two thousand six hundred and fifty-nine cases came under treatment, and one thousand seven hundred and thirty-nine patients had open lesions which were subjected to one or more dark-field examinations. Some of the patients with negative dark-fields subsequently proved to be cases of syphilis, and some did not. With these, we are not at present concerned. Every genital sore and many extra-genital ones were given a dark-field examination. Of these examinations, two hundred and fifty-five or 15 per cent of the total number of patients examined by this method, gave positive results. As many as three examinations were made on as many successive days of a single case before a positive result was obtained, with a total of two hundred and eighty-one in all for the two hundred and fifty-five patients.

Positive results were obtained from extra-genital lesions on the back of the neck, lips, eyelid, face, trunk, tongue, mucous patches in mouth, on tonsils, and about anus. With the exception of those on the lip and the one on the back of the neck, these were practically all secondary manifestations, and all of them gave a positive Wassermann test of the blood.

The genital lesions, as would be expected, were much more numerous. There were one hundred and ninety-six on the penis, eleven

within the urethra or at the meatus, two on the scrotum, and one on the mons pubis. These were practically all primary lesions, and one hundred and twenty-one, or 50 per cent, gave a negative Wassermann reaction.

Seventy-six in all, or 30 per cent of the total, presented themselves after the completion of the first course for further examination and treatment. Of these, seventy appeared in the first six months.

I will not bore you with a detailed analysis of the whole two hundred and fifty-five cases, but will proceed at once to the consideration of those patients who returned and about whom we therefore have some subsequent data. The accompanying table will show at a glance how these seventy-six cases have been classified.

TABLE OF WASSERMANN TESTS MADE AFTER TREATMENT

	1st 6 Mos	2nd 6 Mos	2nd Year	3rd Year	4th Year	5th Year
Wassermann test, positive at start, became negative	28	8	11	2	0	0
Wassermann test, positive at start, remained positive	10	11	1	1	0	0
Wassermann test, negative at start, became positive	2	1	1	1	0	0
Wassermann test, negative at start, remained negative throughout	30	12	7	3	1	1

*Note.* Six patients presented themselves, for the first time after treatment, in the second six months or later. This accounts for an apparent discrepancy in the text.

Forty of these return cases had had positive blood Wassermann tests and positive dark-fields before treatment was begun. By the end of the first or second six months the blood reaction of twenty-nine had become negative, while eleven remained positive. The twenty-nine cases showed varying results as time went on and they received or did not accept further treatment. In some, the reaction of the blood became negative and, as far as we know, remained so. In others, the blood reaction would at one time be negative and at others positive, following the usual course of well established secondary syphilis.

Thirty-three of these seventy-six return cases had had negative blood Wassermann tests but positive dark-fields before treatment was begun. Of these, thirty-one, or 94 per cent, still had negative blood reactions at the end of the first six months. Eleven returned at the end of the second six months, and so on

# THE ROLE OF THE DARK FIELD IN THE DIAGNOSIS OF SYPHILIS, WITH REPORT OF 255 POSITIVE CASES\*†

By J P THORNLEY, M D, FRANK VERO, M D, and SAMUEL HALPERN, M D, NEW YORK, N Y

From the Department of Dermatology and Syphilology, U S Marine Hospital, No 70 Surgeon General, U S Public Health Service Published with the permission of the

**T**HE importance of a prompt diagnosis of syphilis in any of its stages cannot be too strongly emphasized. The necessity for a quick diagnosis is in direct proportion to the duration of the disease, yet even in the later stages where important structures are threatened, a delay of a few hours may make all the difference between the preservation of a useful life or a resulting utter failure. As Stokes in his recent work so ably puts it, "the saving of a day increases the physician's lead on the disease to an unknown extent."

Without a doubt the various blood reactions will, for a long time to come, remain the chief reliance of the physician for the confirmation of the diagnosis of syphilis in its later stages and for the discovery of the latent and asymptomatic cases. Here we attempt to check the ravages of a disease already established and to eradicate it if possible. The conditions are entirely different when we are called upon to treat a case at its beginning. Here the possibility of eradicating the disease before it has done irreparable damage is great, and we should be urged by every sense of duty and humanity to use every reliable means at our disposal to diagnose accurately the initial lesion before the serum reactions have changed from negative to positive.

Fortunately we have at least one method which is fairly easy and reasonably reliable. It is the examination of the serum obtained from a suspected sore, a swollen gland, or a suspicious eruption by means of the dark field. The method is not infallible, and has its limitations, just as the examinations for the tubercle bacillus and many other organisms have their limitations. As with them, it is necessary to obtain a satisfactory specimen for examination, and a negative result is not conclusive, yet both these handicaps can be materially reduced by conscientious care and a very moderate amount of skill and experience. We can hope to find the spirochetes in open lesion even when the disease is several years old, and we can reasonably expect to find them in the primary and the early secondary lesions when there has been no recent local antiseptic treatment or constitutional treatment with arsphenamin or bismuth.

It is to emphasize the importance of diagnosing the disease before the serum reactions have changed that this article has been written,

and it is to that point that we wish to invite your attention. A host of writers, among whom should be mentioned Howard Fox, Fordyce, Stokes, Klauder, Dourmaskin, Rosen, Abramowitz, and others, have repeatedly called attention to the importance of the dark field in the diagnosis of syphilis. Fordyce\* states, that "in primary syphilis when the spirochetes are demonstrated and the Wassermann reaction is negative, it is possible to cure syphilis with salvarsan alone." In this connection we wish to cite as possible cures, but subject to future developments, thirty-one cases of our own.

It is not the purpose of this paper to go into the technique of the dark field examination, as it has been minutely described in many excellent text-books and can be easily and quickly mastered under the direction of a competent and experienced teacher.

Before taking up the analysis of our result at Marine Hospital No 70, it would be well to give an idea of the class of patients we treat and the routine treatment we have been obliged to adopt. The patients are practically all sailors, here today and gone tomorrow. With the help of the Social Service, we can usually induce them to take one complete course, sometimes two and even three. With the increasing prestige of the hospital and the resulting confidence of the patients, this follow-up of the treatment by the patients themselves is becoming more and more satisfactory every day. On the other hand, the establishment of a definite follow-up system that would function satisfactorily or would pay in results seems to be an impossibility. We sent out fifty follow-up letters to as many of our dark-field patients, with the result that not one single patient replied or showed up for examination. Almost all of the letters were returned by the post office department as "undelivered," showing quite conclusively the futility of any effort to keep a systematic check upon results. It is for that reason this report is lacking in a complete and scientific ending of most of the cases. As a rule, it is those patients who have some reason to suspect that the disease is still active whom we have the chance to further examine. I also think it is quite evident that any attempt to direct the treatment of our patients after leaving the hospital would be futile and doomed to failure in fully 70 per cent of the cases. We

† Diagnosis and General Treatment of Syphilis by John A Fordyce, M D. The American Journal of the Medical Sciences Oct. 1916 Vol. 152 pp. 469-489

## AN EXPERIMENTAL STUDY OF CERTAIN FACTORS INFLUENCING OSTEOGENESIS\*

By JOHN J. MORTON, M.D., and SAMUEL J. STABINS, M.D., ROCHESTER, N. Y.

From the Department of Surgery School of Medicine and Dentistry University of Rochester

**I**NTRODUCTION The process of calcification and the healing of fractures by callus have always held a fascination for the student of biological growth. Discoveries in experimental cancer research seem to indicate that certain factors must be fulfilled before growth of any kind takes place. It was thought that perhaps the influence of some of these factors could be demonstrated visibly by the use of Roentgenograms when the growth repair of bone was under consideration.

The following experiments were accordingly undertaken and the present report is one of the impressions gained to date. The work is as yet by no means completed as the number of animals is small, and the data meagre. Additional researches are being carried out, and the conclusions may be modified at a later date, when sufficient time has elapsed and a larger number of observations have been made.

**Procedure (1) Ligation of Saphenous Vein—Resection** Four albino rats were given ether anesthesia, and under aseptic precautions one-half centimeter of the mid portion of the fibula was removed on each leg at the same level. The periosteum was not reflected and no attempt was made to preserve it. The right leg was kept as the control leg but the saphenous vein was identified, ligated, and divided in the left leg. Since the intact tibia served as an excellent splint, no restriction was put on the use of the limbs of these animals. Healing took place by first intention in all the animals. Roentgenograms were taken to follow the progress of calcification. In six weeks the bone had united in the control leg but no union had taken place in the leg with the partial blocking of the venous system, although the space between the bone ends was reduced in amount.

In a similar manner, one-half centimeter of the fibula was removed at an equally measured distance from the upper end of the bone in three dogs. The periosteum, however, was reflected and preserved in these animals. The right leg again served as the control and the saphenous vein was ligated and divided in the left leg. (The saphenous vein enters the common femoral in the lower third of the dog's leg; it is accompanied by an artery and a nerve. These latter were preserved intact.) Roentgenograms taken at intervals showed solid healing on the control leg after nine weeks but a failure of union on the left leg with the ligated saphenous vein. The bones were explored and removed for study in two of these

animals and the non-union verified. Microscopic sections of the control and the non-united bones showed little difference in the picture except in degree. Osteogenesis was taking place in a normal manner on the control side but it had not advanced so far on the non-united side, the slides containing more cartilage and osteoid tissue.

**(2) Ligation of Saphenous Vein—Fracture** Exactly the same procedure was carried out in two dogs with the exception that a simple fracture was made instead of a resection of bone. The control side healed in seven weeks but no union took place on the experimented side. The bones were explored and removed in one of these animals and the failure of union demonstrated.
